# 1 Introduction

This technical report describes the noise modeling conducted for San Antonio Airspace Modernization Project Environmental Assessment (Draft EA). This report contains:

- Objectives in modeling noise analysis for the Draft EA (**Section 2**)
- Noise modeling background and inputs (**Section 3**)
- Noise modeling procedures (**Section 4**)
- Noise analysis (**Section 5**)
- Supplements (**Section 6**)

The following describes the criteria used to identify potential noise impacts. Further information on the fundamentals of noise is provided in the EA (see Appendix F, *Basics of Noise*).

## 1.1 Noise Impact Criteria

The Federal Aviation Administration (FAA) has considered and identified threshold levels above which aircraft noise causes an adverse impact to people. The agency has determined that a significant impact occurs if a proposed action would result in an increase of Day-Night Average Sound Level<sup>1</sup> (DNL) 1.5 decibels (dB) or higher on noise-sensitive areas exposed to DNL 65 dB or higher levels.

In 1992, the Federal Interagency Committee on Noise (FICON) recommended that noise increases of DNL 3 dB or higher in areas with exposure levels between DNL 60 and 65 dB be evaluated in environmental studies when increases of DNL 1.5 dB or higher occur at noise-sensitive locations with exposure levels at or above DNL 65 dB. Increases of this magnitude in areas with noise exposure levels below DNL 65 dB are not to be considered as “significant impacts,” but are reportable changes and receive further consideration. FICON’s recommendation has been adopted by the FAA into FAA Order 1050.1F, *Environmental Impacts: Policies and Procedures*.

In 1990, the FAA issued a noise screening procedure for determining whether certain airspace actions at or above 3,000 feet (ft) above ground level (AGL) might result in increases to DNL levels of 5 dB or higher. The noise screening procedure was issued in response to FAA experience that increases in noise of DNL 5 dB or higher at cumulative levels well below DNL 65 dB could be disturbing to people and become a source of public concern. In the Environmental Impact Statement (EIS) for the Expanded East Coast Plan (EECP), the FAA evaluated noise levels down to the DNL 45 dB level for potential increases in DNL noise exposure of 5 dB or higher. In the EECP study, the FAA determined that the DNL 45 dB level is the minimum level at which noise needed to be considered because “even distant ambient noise sources and natural sounds such as wind in trees can easily exceed this (DNL 45 dB) value.”<sup>2</sup> This threshold of change was subsequently used in the Chicago Terminal Airspace

---

<sup>1</sup> The DNL metric represents noise as it occurs over a 24-hour period, with one important exception: DNL treats noise occurring at night differently from daytime noise. In determining DNL, the metric assumes that the A-weighted levels occurring at night (defined as 10 p.m. to 7 a.m.) are 10 dB louder than they actually are. This 10-dB increase is applied to account for the fact that there is a greater sensitivity to nighttime noise, and the fact that events at night are often perceived to be more intrusive because nighttime ambient noise is less than daytime ambient noise.

<sup>2</sup> U.S. Department of Transportation, Federal Aviation Administration, Expanded East Coast Plan – *Changes in Aircraft Flight Patterns Over the State of New Jersey*, pp. 5-9. 1995.

Project (CTAP) EIS and the Potomac Consolidated TRACON Airspace Redesign EIS. FAA Order 1050.1F memorialized the formal guidelines for evaluating noise impacts.

Increases of DNL 3 dB between DNL 60 and 65 dB and of DNL 5 dB between DNL 45 and 60 are considered reportable changes when evaluating air traffic actions such as the Proposed Action. The increase in noise at these levels may be enough to be noticeable and potentially disturbing to some people, but the cumulative noise level is not high enough to constitute a “significant impact.” **Table 1** summarizes the criteria utilized to assess the level of change in noise exposure attributable to the alternative scenarios discussed in the Draft EA.

**Table 1 Criteria for Determining Impact of Increases in Aircraft Noise**

| DNL Noise Exposure Level | Increase in DNL with Proposed Action | Aircraft Noise Exposure Change Consideration              |
|--------------------------|--------------------------------------|---|
| DNL 65 and higher        | DNL 1.5 dB or higher <sup>1</sup>    | Exceeds Threshold of Significance                         |
| DNL 60 to 65             | DNL 3.0 dB or higher <sup>2</sup>    | Information Disclosed When Evaluating Air Traffic Actions |
| DNL 45 to 60             | DNL 5.0 dB or greater <sup>3</sup>   | Information Disclosed When Evaluating Air Traffic Actions |

## 2 Noise Analysis Objectives

The San Antonio Airspace Modernization Project presents a detailed exercise in noise modeling for the following airports:

- San Antonio International Airport (SAT)
- New Braunfels National Airport (BAZ)
- Randolph Air Force Base Airfield (RND)
- Kelly Field (SKF)

The following sections describe the objectives identified to determine that the noise analysis provided a detailed and accurate assessment of noise exposure throughout the General Study Area, and other supplemental areas as defined and identified.

### 2.1 Evaluate Changes in Noise Levels

The FAA has developed specific guidance and requirements for the assessment of aircraft noise to comply with National Environmental Policy Act (NEPA) requirements. This guidance, specified in FAA Order 1050.1F, requires that aircraft noise be analyzed in terms of the annual DNL metric. In practice, this requirement means that DNL levels are computed for the Average Annual Day (AAD) of operations for the year of interest. An AAD represents all the aircraft operations for each day in a study year divided by 365, the number of days in a year. The AAD does not reflect a particular day, but is meant to represent a typical day over a period of a year.

Beyond requiring the use of the DNL metric, the FAA endorses the use of supplemental noise metrics on a case-by-case basis to describe aircraft noise impacts for specific noise sensitive locations. No supplemental noise metrics were determined to be necessary for the Draft EA.

Typical noise studies use noise exposure contours (typically color-coded lines on a base map delineating DNL 5dB increments) to describe noise impacts only in the immediate vicinity of airports (three to five miles). Wide area air traffic noise models use georeferenced receptors, which can provide more detailed results to evaluate the effects of high-altitude airspace changes from the ground level up to 18,000 ft AGL on noise-sensitive areas and to determine if more detailed NEPA analysis may be required. For this Draft EA, a detailed set of receptors was used to analyze current and future noise in the General Study Area (details regarding the creation of the General Study Area are discussed in the Draft EA Section 1.2 *General Study Area*). An additional supplemental boundary area (18,000 Foot Supplemental Study Area) including aircraft traveling up to 18,000 feet AGL was analyzed for assessing potential impacts to Section 4(f), Historic and Cultural Resources, and Wildlife only. An additional screening area (SNIDR Supplemental Study Area) was added in order to perform a noise screening for associated dependent utility procedure elements for the proposed SNIDR Standard Instrument Departure (SID) discussed in the Draft EA Chapter 3. This SNIDR Supplemental Study Area is defined as a polygon with vertices at the SMAKR, WEMAR, GMANN, and BELLR waypoints. This area overlaps and extends out of the General Study Area as well as the 18K Supplemental Area. Additional Section 4(f) resources and historic and cultural resources (see **Section 2.3.2**) and 0.5 nautical mile (NM) evenly spaced grid points (See **Section 2.3.3**) were added to cover this screening area.

Details regarding the receptors, and groups of receptors called receptor sets, used for the Draft EA are discussed in **Sections 3.1.13** and **3.2.11**.

The following scenarios were evaluated:

1. 2021/2022 Existing Conditions – routes as flown in the time period spanning 03/01/2021 through 02/28/2022
2. 2023 Future No Action – routes as forecasted to be flown in the year 2023 if no Proposed Action airspace changes were implemented
3. 2023 Future Proposed Action – routes as forecasted to be flown in the year 2023 if the Proposed Action changes are implemented
4. 2028 Future No Action – routes as forecasted to be flown in the year 2028 if no Proposed Action airspace changes were implemented
5. 2028 Future Proposed Action – routes as forecasted to be flown in the year 2028 if the Proposed Action changes are implemented

The information disclosed in this study includes the maximum potential number of people exposed to DNL changes that meet or exceed the thresholds stated in **Table 1** for the scenarios previously listed.

## **2.2 Model All Traffic Routes**

### **2.2.1 General Study Area**

For this effort, radar data from both the FAA Performance Data Analysis and Reporting System (PDARS) and the FAA System Wide Information Management (SWIM) for March 1, 2021 through February 28, 2021 was obtained and processed. Overall, 180,460 radar flight tracks were used to evaluate and model typical flight routes and flows throughout the General Study Area. The set of radar flight tracks included all military and civilian Instrument Flight Rules (IFR)<sup>3</sup> flights that operated at or below 10,000 feet AGL in the General Study Area and at or below 18,000 feet AGL within the 18,000 Foot Supplemental Study Area.

### **2.2.2 Between General Study Area Boundary and 18,000 Foot Supplemental Study Area**

Radar flight tracks were used to evaluate and model flight routes in areas beyond the General Study Area boundary up to where IFR aircraft operate at or below 18,000 feet AGL (18,000 Foot Supplemental Study Area). FAA Order 1050.1F, *Environmental Impacts: Policies and Procedures, Appendix B, Section B-1.3*, provides that the study area for the noise analysis of a proposed change in air traffic procedures may extend up to 18,000 feet AGL if the proposed action is over a national park or wildlife refuge where other noise is very low, and a quiet setting is a generally recognized attribute.

---

<sup>3</sup> Aircraft operate under two distinct categories of flight rules: Visual Flight Rules (VFR) and Instrument Flight Rules (IFR). These flight rules generally correspond with two categories of weather conditions: Visual Meteorological Conditions (VMC) and Instrument Meteorological Conditions (IMC). VMC generally exist during fair to good weather with good visibility. IMC occur during periods when visibility falls to less than three statute miles or the ceiling (the distance from the ground to the bottom layer of clouds when the clouds cover more than 50 percent of the sky) drops to lower than 1,000 feet. Under VFR, pilots are able to fly whatever route they choose and are responsible to “see and avoid” other aircraft and obstacles such as terrain to maintain safe separation. Under IFR, ATC is responsible for providing separation from other aircraft and terrain, and pilots use cockpit instruments and radar to fly routes specified by ATC and to comply with ATC instructions. Pilots must follow IFR during IMC; however, due to various factors such as the general requirement for aircraft to operate under IFR in Class A airspace [i.e., en route airspace between 18,000 and 60,000 feet above Mean Sea Level (MSL)], the majority of commercial air traffic operates under IFR regardless of weather conditions.

## 2.3 Model Day & Night Noise Levels

### 2.3.1 Population Centroids

Within the General Study Area, a total of 46,954 individual population points were evaluated, representing a total population of 3,574,471 people. These points, each of which represents a specific number of people, are referred to as population centroids. Each centroid represents a census block, the smallest geographical unit for which the U.S. Census maintains population data. The smallest centroid has a population of one, and the largest centroid has a population of 5,052. Centroid locations and population counts were drawn by the U.S. Census Bureau based on 2020 U.S. Census data. For each of the five modeling scenarios (see **Section 2.1**), AAD DNL values were calculated at all population centroids within the General Study Area. **Exhibit 1** depicts the census block centroid points modeled within the General Study Area.

### 2.3.2 Section 4(f) Resources and Historic and Cultural Resources

A grid point analysis was also performed to evaluate noise levels at sites or lands potentially protected under Section 4(f) of the Department of Transportation Act of 1966 (49 U.S.C. § 300 et seq.) (herein referred to as Section 4(f) properties or resources). For the purposes of this analysis, Section 4(f) resources include Section 106 historic resources listed or eligible for listing on the National Register of Historic Places under the National Historic Preservation Act (NHPA) of 1966 (16 U.S.C. § 470 et seq., as amended). The Section 4(f) sites were initially identified as single point locations within the 18,000 Foot Supplemental Study Area and SNIDR Supplemental Study Area. In some cases, the Section 4(f) properties covered a large area (usually large parks or wilderness areas) that were not well represented by a single analysis point. In these cases, a uniformly spaced grid of points was defined over each area to provide adequate coverage. **Exhibit 2** depicts the grid points modeled for Section 4(f) resources in the 18,000 Foot Supplemental Study Area.

A grid point analysis was also performed to evaluate noise levels as applicable at national parks, national wildlife refuges, and national wilderness areas that are outside of the General Study Area, but within the 18,000 Foot Supplemental Study Area. These points are included in **Exhibit 2**.

### 2.3.3 0.5 NM Evenly Spaced Grid Points

Another grid point analysis was performed to encompass the 18,000 Foot Supplemental Study Area and SNIDR Supplemental Study Area. This analysis was done to capture the noise level changes in areas not covered by other grids. Grid points used for this analysis were evenly spaced in one-half NM intervals. **Exhibit 3** depicts the 0.5 NM Evenly Spaced Grid Points.

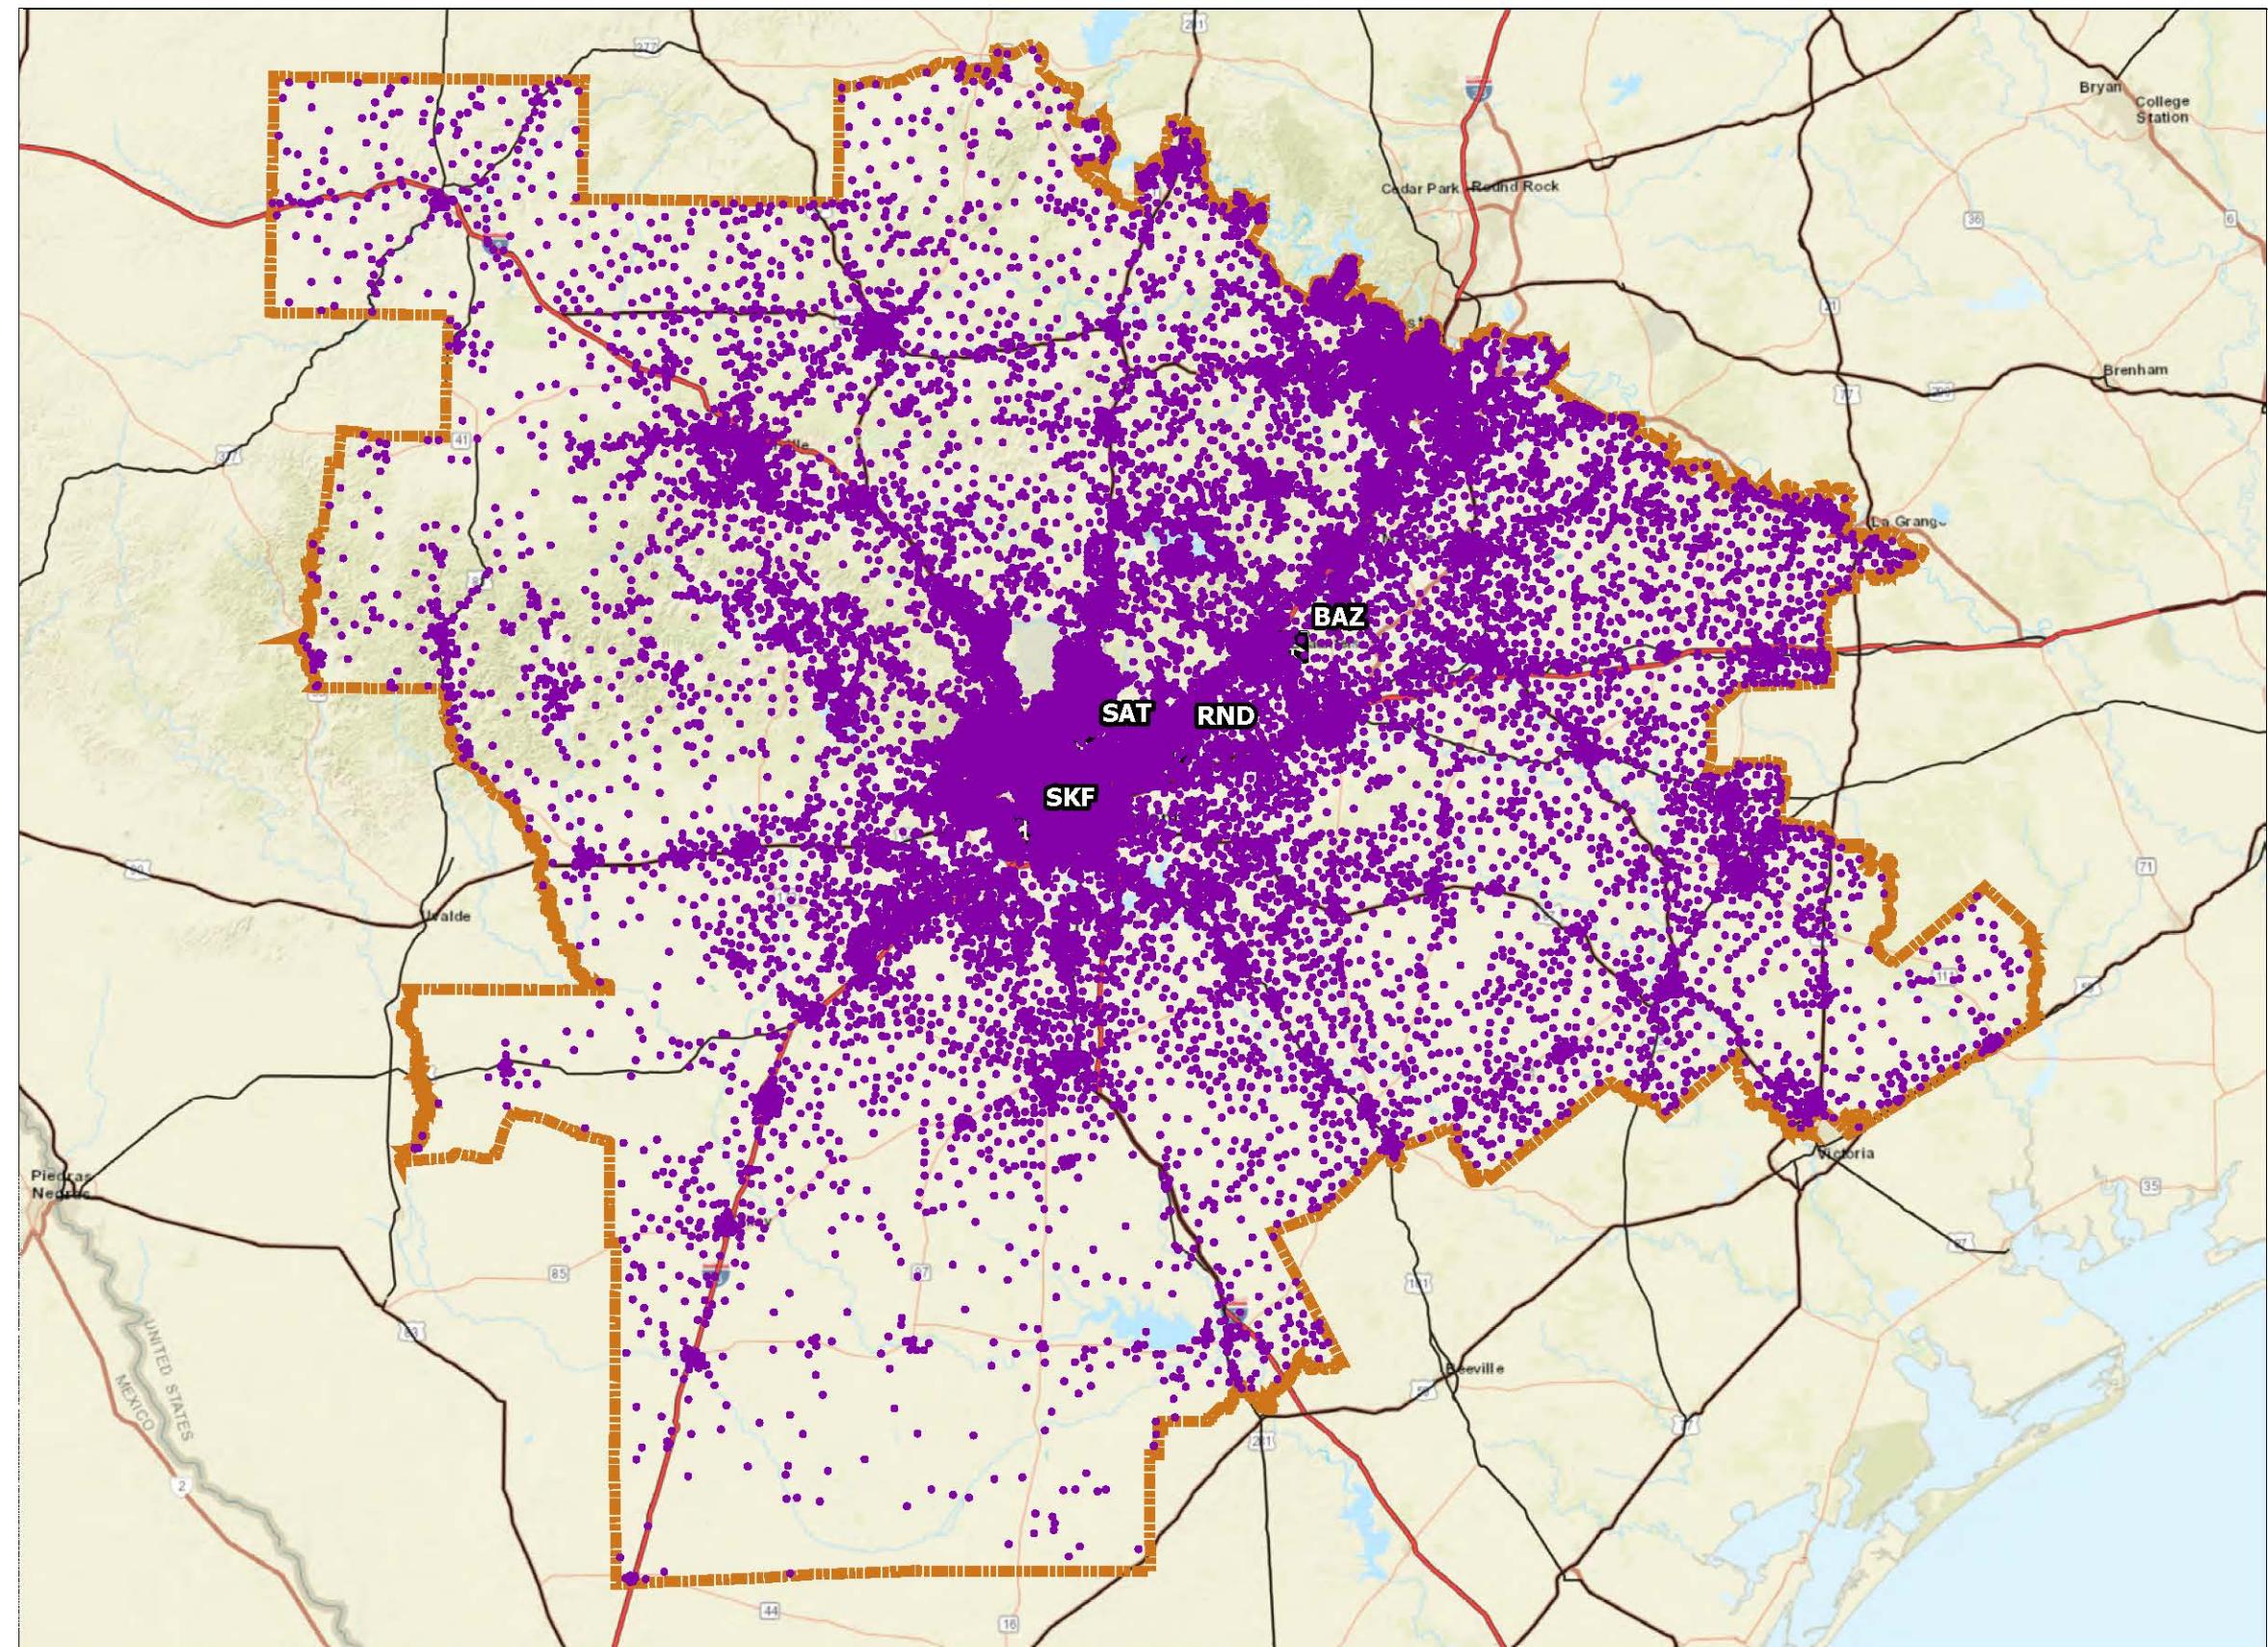

### 2.3.4 Noise Sensitive Land Use Areas

Order 1050.1F Appendix B requires the FAA to identify the location and number of noise sensitive uses in addition to residences that could be significantly impacted by noise. As defined in Paragraph 11-5b(10) of Order 1050.1F, a noise sensitive area is:

“an area where noise interferes with normal activities associated with its use. Normally, noise sensitive areas include residential, educational, health, and religious structures and sites, parks, recreational areas, areas with wilderness characteristics, wildlife refuges, and cultural and historical sites.”

The compatibility of noise sensitive uses is evaluated through comparison with the compatibility guidelines provided in 14 CFR Part 150, Appendix A, Table 1. The guidelines focus on areas exposed to noise levels of DNL 65 dB and greater.

The locations of these noise sensitive land use areas were identified and discussed in more detail in the Draft EA Chapter 4, Section 4.2.1.3 *Noise Sensitive Areas and Uses*. **Exhibit 4** depicts the grid points identified to represent the noise sensitive land use areas.

## **2.4 Use Standard Profiles with Targeted Altitudes**

Aircraft within the General Study Area operate in accordance with standardized air traffic control procedures. To model existing and proposed procedures, aircraft profiles were designed to meet target altitudes along the trajectory. These targeted altitudes were set by either air traffic control, airspace procedure restrictions, or recommended and approved by subject matter experts. See **Sections 3.1.8** and **3.2.8** for details.

## **2.5 Identify and Quantify Noise Changes and Causes Thereof**

DNL noise levels were calculated for each centroid and grid point, and differences in noise exposure between the Proposed Action and the No Action for each of the future analysis years were quantified. Any significant or reportable noise changes would be explained in **Section 5**. The criteria set to meet this objective are described in **Section 1.1, Noise Impact Criteria**.

## **2.6 Produce Easily Interpreted and Informative Tables and Graphics of Results**

The complexity (number of flight routes, airports, operations, etc.) of the study created challenges in reporting noise modeling results in a useful format for analysis. Tables and graphics were designed to provide data that would be understandable to the general public.

**THIS PAGE INTENTIONALLY LEFT BLANK**

### 3 Noise Modeling Background & Inputs

The FAA requires that aircraft noise be evaluated using authorized computer noise models. This project includes two civilian airports (SAT and BAZ), one military airfield (RND), and one joint-use military/civilian airfield that hosts primarily military aircraft. For this reason, two separate noise modeling tools were used. For SAT and BAZ, the Aviation Environmental Design Tool (AEDT) version 3d model was used. RND is located on a United States Air Force Base (Randolph Air Force Base, a subunit of Joint Base San Antonio [JBSA]) and SKF has a small civilian and primarily military presence, thus their flight schedules, types of operations, and aircraft are primarily military. From consultations with the FAA Office of Environment and Energy, it was decided that modeling of RND and SKF be performed using NOISEMAP. As a result, this section segregates noise modeling inputs by the respective civilian (AEDT) and military (NOISEMAP) authorized noise models.

Using two noise modeling tools for a single effort requires modeling inputs to vary. Effort was made to keep inputs and assumptions between the models as consistent as possible. Outputs were normalized using FAA-approved tools and methods to aggregate results to AAD DNL values.

#### 3.1 AEDT

Noise modeling in AEDT requires several types of input data including airport/runway locations, local environmental variables, operational levels, day/night distributions, runway usage, fleet mix, noise-power-distance relationships, climb/descent profiles, aircraft stage lengths, flight track definition and assignment, user-defined profiles, and receptor sets. Details of the AEDT input data for the Draft EA are discussed below.

##### 3.1.1 Model Background

AEDT is the FAA's regulatory noise modeling tool for air traffic actions such as those proposed for the San Antonio Airspace Modernization Project. AEDT is a software tool suite that models airspace traffic and its environmental effects for a range of scenarios from a single local flight to numerous global flights. By modeling aircraft performance in space and time, AEDT generates results for fuel consumption, emissions, noise, and air quality for the purposes of evaluating environmental impacts. AEDT leverages the use of geographic information system (GIS) and relational database technology to provide the necessary scalability and flexibility to accommodate the size and detail of regional airspace studies.

AEDT provides a powerful computational environment and graphical user interface, and provides the following major capabilities:

- Provides automated quantitative comparison of noise impacts across alternative airspace designs
- Imports and displays track and operation data from airspace models, and population and community data from other sources
- Enables users to specify air traffic control altitudes and automatically calculates required aircraft thrusts and speeds necessary for noise calculations
- Calculates predicted noise impacts at all population centroids (or other specially defined points) in large study areas
- Provides automated means of annualizing noise impact based on different operational configurations and/or runway usage statistics

- Identifies and maps all areas of change in noise impact
- Assembles tables and figures for noise-impact data analysis and report generation
- Applies multiple layers of data checking and quality control

AEDT has been identified as the officially-endorsed FAA tool for environmental modeling and analysis metrics (noise, fuel burn, and emissions) for regional airspace redesign/analysis projects. The official release of the initial AEDT 2a was on March, 21, 2012. Since then, subsequent versions of AEDT have been released. The San Antonio Airspace Modernization Project noise modeling was started in March 2022. FAA guidelines require that all FAA actions requiring noise, fuel burn, or emissions modeling and for which the environmental analysis process began on or after March 29, 2021 are required to use AEDT 3d.<sup>4</sup> To conform with these guidelines, the noise modeling for the San Antonio Airspace Modernization Project uses AEDT 3d.

### **3.1.2 Airport and Runway Data**

**Table 2** identifies the airports and runway end names modeled. In total, two airports within the General Study Area were evaluated. All runways at these airports were assumed to be available for traffic assignments in AEDT.

**Table 2 Study Airport Details - AEDT**

| Airport Name                      | Code | Location             | Runway End Names <sup>1</sup> |
|-----------------------------------|------|----------------------|-------------------------------|
| San Antonio International Airport | SAT  | San Antonio, Texas   | 31L, 31R, 13L, 13R,<br>22,4   |
| New Braunfels National Airport    | BAZ  | New Braunfels, Texas | 17, 35, 13, 31                |

*1 A runway can be used in both directions but is named in each direction separately. Runway number is based on the magnetic direction of the runway (e.g., Runway 09 points to the east direction). The two numbers on either side always differ by 180 degrees. If there is more than one runway pointing in the same direction, each runway number includes an L, C, or R at the end. This is based on a runway's position relative to others in the same direction – left, center, or right.*

Prepared by: ATAC Corporation, August 2022.

### **3.1.3 Local Environmental Variables**

To calculate noise levels specific to the conditions in the General Study Area, 18,000 Foot Supplemental Study Area, and SNIDR Supplemental Study Area, the AEDT model uses various local environmental variables such as temperature, pressure, dew point, humidity, and wind speed. This meteorological data is available for many weather stations in AEDT's airport database.

Detailed terrain data for the General Study Area, 18,000 Foot Supplemental Study Area, and SNIDR Supplemental Study Area were incorporated from the United States Geological Study (USGS) 1-degree National Elevation Dataset (NED).<sup>5</sup> NED is a digital elevation model with consistent grid-spacing of 1-arc-second (~30 meters) for 1-by-1-degree tiles covering the United States.<sup>6</sup>

---

<sup>4</sup> Per the FAA AEE memo dated September 27, 2017, "Guidance on determining which version of the Aviation Environmental Design Tool (AEDT) to use for FAA actions and studies," the latest version of AEDT becomes the approved model upon its release.

### 3.1.4 Operation Levels and Day/Night Distribution

IFR operation levels (number of takeoffs and landings) for each Study Airport were based on radar data, historical airport counts from FAA sources including the Operations Network (OPSNET),<sup>7</sup> Traffic Flow Management System Counts (TFMSC),<sup>8</sup> and Terminal Activity Forecasts (TAF)<sup>9</sup> developed for this analysis. Investigating radar data showed IFR helicopter traffic rarely, if ever, flew traffic patterns, airspace procedures, or exceeded 10,000 ft MSL. As a result, helicopter operations and trajectories were excluded from the project.

Forecasts are presented in Appendix H: the *Flight Schedules Tech Report* technical report. The information contained in these forecasts and used for noise modeling includes the type of aircraft, origin and destination airports, daytime or nighttime operation time, and the average number of daily operations. The detailed operation tables which comprise the forecast were developed for the forecast years 2023 and 2028. For this analysis, each forecast represents the average day (annual/365) of traffic for the year of interest. **Table 3** presents the IFR operation totals modeled for the Draft EA.

**Table 3 Modeled Average Annual Day IFR Operation Totals**

| Airport | Existing Conditions<br>(03/2021 – 02/2022) |       | 2023  |       | 2028  |       |
|---------|--|-------|-------|-------|-------|-------|
|         | Day  | Night | Day   | Night | Day   | Night |
| BAZ     | 22.2                                       | 0.8   | 22.6  | 0.8   | 22.9  | 0.8   |
| SAT     | 306.5                                      | 51.3  | 380.3 | 68.3  | 419.6 | 77.4  |

Prepared by: ATAC Corporation, August 2022.

### 3.1.5 Runway Use

Generally, the primary factors determining runway use at an airport are weather and prevailing wind conditions at the time of a flight. Additionally, several secondary factors influence runway selection. These factors include runway safety issues (e.g., taxiing aircraft crossing active runways or Land and Hold Short (LAHSO)<sup>10</sup> rules), the current composition of the traffic (many arrivals or many departures), and even the flight origin or destination. This latter factor is also based on safety in that traffic is easier to sort on the ground (taxi for direction) than it is in the air.

Typically, arriving and departing aircraft are assigned to a specific fix. These fixes, in turn, may have a preferred arrival or departure runway assignment and a secondary arrival or departure runway assignment. As controllers balance delay and runway utilization by time of delay based on demand, there are times when arriving and departing aircraft are diverted to a secondary runway. This is especially true when an airport has multiple parallel runways. This allows the airfield to operate in the safest and most efficient manner.

It is important to note that within the context of all of these factors, future runway use at an airport is, at best, an estimate. Simple changes over time, such as airlines changing the markets (destinations) that they serve, can have a notable effect on actual runway use in the future.

**Table 4** presents airport runway operating configuration usage for SAT based on analysis of 2021/2022 historical data (graphically, see Draft EA Exhibit 1.3). The runway operating configuration refers to the direction a runway is used for arrivals and departures, which can vary based on the direction of prevailing winds.

**Table 4 SAT Runway Operating Configuration**

| Operating Configuration | Main Arrival Runways | Main Departure Runways | Percentage |
|-------------------------|----------------------|------------------------|------------|
| Southeast               | 13R                  | 13R                    | 41.9%      |
| Mixed                   | 13R                  | 13R, 04                | 27.1%      |
| Northeast               | 04                   | 04                     | 13.0%      |
| Northwest               | 31L                  | 31L                    | 14.2%      |
| Southwest               | 22                   | 22                     | 3.8%       |

Source: PDARS Data (03/01/2021-02/28/2022), SWIM Data (03/01/2021-02/28/2022)

Prepared by: ATAC Corporation, August 2022

**Tables 5 and 6** present summaries of the modeled airport runway use percentages for BAZ and SAT arrivals and departures respectively, by daytime and nighttime, for the No Action and Proposed Action. The proposed air traffic procedures do not change runway use; therefore, the distribution of operations was held constant between No Action and Proposed Action.

The average annual runway use under 2021/2022, 2023, and 2028 conditions reflects average runway usage as sampled over 364 days from 03/01/2021-02/28/2022, providing a representative statistical sampling of existing conditions runway usage.<sup>11</sup> Data from 2/3/2022 was excluded from the analysis due to anomalous operations counts as a result of a significant cold weather event impacting regularly scheduled operations in the San Antonio area. One day of data was removed from the analysis due to anomalous operations counts. The average annual runway use for the Study Airports as presented in **Table 5** and **Table 6** for 2023 and 2028 No Action is based on historical runway use over a period from March 1, 2021 through February 28, 2021. The average annual runway use for 2023 and 2028 Proposed Action is based on estimates provided by air traffic controllers associated with anticipated changes in airport runway operating configuration use with the new procedures in place. As depicted in the tables, runway use is not notably different between No Action and Proposed Action. Note that differences in configuration use between those used in this study and other studies may result, given the use of different time periods to derive the No Action configuration use and, as a result, assumptions about future configuration use.

<sup>11</sup> See Draft EA Chapter 4, Section 4.2.1.1 Noise Modeling Methodology.

### **3.1.6 Aircraft Fleet Mix**

Fleet mix assumptions were developed for the Draft EA as part of the forecasting effort. **Tables 7** and **8** present the forecasted fleet mixes for 2023 and 2028 for operations at BAZ and SAT for both the No Action and Proposed Action. This table presents the aircraft types as used in the AEDT model. Not all specific aircraft types that were present in the forecast are available aircraft types in the AEDT model. For those cases, FAA-approved substitutions provided in AEDT were chosen. For aircraft not listed in AEDT as approved substitutions, a proposed AEDT aircraft type based on similar operating and noise characteristics was chosen and approved by the FAA. The letter to the FAA requesting approval of these substitutions and the response from the FAA are included with this technical report as **Supplement 1**.

### 3.1.7 Aircraft Noise-Power-Distance (NPD) Curves

AEDT uses tables of noise vs. power vs. distance data to represent noise levels for a given power setting (or thrust setting) at a range of distances from the aircraft to a receptor. The data consists of a set of sound exposure levels in decibels for various combinations of aircraft, engine power settings, and distances from the aircraft to a receptor. This NPD data is available for many aircraft and is stored in AEDT's fleet database.

The NPD data is accessed during AEDT noise calculations to determine the noise levels for the appropriate metric at each receptor. The contribution of each modeled operation to each receptor is calculated, then aggregated across all operations to measure the noise exposure of a given set of operations.<sup>12</sup>

### 3.1.8 Aircraft Climb/Descent Profiles

To accurately model noise exposure, AEDT has the capability to include specified altitude control codes on flight trajectories, allowing users to constrain modeled trajectories as necessary. These altitude controls reflect altitude information provided by air traffic procedure design. AEDT generates climb/descent profiles for each operation that are consistent with specified altitude control codes within the constraints of the allowable aircraft performance determined by AEDT.

Altitude control codes are only applied above altitudes of 3,000 feet above field elevation (AFE).<sup>13</sup> This means that AEDT will use default profile data 3,000 feet AFE and below. Above 3,000 feet AFE, the profile will follow the altitudes prescribed by the input trajectory in such a manner that the specified altitude control codes are adhered to. For flight tracks that do not reach 3,000 feet AFE, an altitude control code is applied to its highest altitude. The four enumerations of altitude control codes are as follows: no altitude control, model to a specified altitude or higher, model exactly to a specified altitude, and model to a specified altitude or lower. If an operation cannot achieve a specified altitude control code, it will not be modeled. In this case, the user may relax the constraining altitude control code(s) and attempt to model the operation again. This process can be repeated until all operations are successfully modeled by AEDT. Once modeled, the operation's performance includes parameters such as four-dimensional position, speed, and thrust.

### 3.1.9 Aircraft Stage Length

Stage length is the term used in AEDT to refer to the length of the trip planned for each departure operation from origin to destination. The trip length is needed in noise calculations because it influences the take-off weight of the aircraft, which is higher for longer trips, and lower for shorter trips. The great-circle distance and the maximum stage length for a given aircraft is used to determine a stage length for each aircraft operation.

### 3.1.10 Flight Track Definitions

Flight tracks are input into AEDT and developed from a sample of detailed radar data. A radar sample of 365 days between March 1, 2021 and February 28, 2022 was acquired and analyzed. One day of data was removed from the analysis due anomalous operations counts.

<sup>12</sup> U.S. Department of Transportation, Federal Aviation Administration, *Aviation Environmental Design Tool (AEDT) Technical Manual, Version 3d*, March 2021.

<sup>13</sup> U.S. Department of Transportation, Federal Aviation Administration, FAA Notice 7210.360, *Noise Screening Procedures for Certain Air Traffic Actions Above 3,000 Feet AGL*, September 14, 1990

Proprietary software was utilized for the detailed analysis of radar data for BAZ and SAT. The data was separated first by airport and operation type (i.e., arrival, departure). Spatial analysis was conducted to develop bundles (a grouping of tracks representing a traffic flow) of radar tracks based on runway, aircraft category (e.g., jet, prop), and route similarity. The radar track bundling process included a review of the 3-dimensional aspect of each group of radar tracks. Bundles were split as necessary to isolate groups of tracks with restricted climb or descent profiles. Such groups generally represent flights operating along specific ATC climb or descent procedures or via ATC instructions.

Automated spatial analysis calculations were applied to the bundles to calculate primary, or backbone, flight tracks for each radar track bundle. The proprietary software allows for the simultaneous computation of sub-tracks located adjacent to the backbone track. Sub-tracks account for the dispersion of actual flights around the primary flight corridor, based on the distribution of radar tracks within each bundle. The spatial analysis process computes the appropriate number of sub-tracks and distributional factors in combination with the statistical lateral distribution of the radar tracks at many locations along the flight corridor to determine the appropriate spacing between the sub-tracks at each location. The number of sub-tracks and the distributional factor associated with each model track are chosen based on the number of radar tracks in the bundle and their general spread throughout the traffic flow.

FAA Order JO 7400.2N, Procedures for Handling Airspace Matters, Environmental Processing; Chapter 32, Section 2 (7400.2N 32-2-1e.2.(b)) recommends the analysis of project-related noise impacts in areas where IFR aircraft operate between 10,000 feet AGL and 18,000 feet AGL (above ground level) when a national park or wildlife refuge is present. To comply with this recommendation, all flight tracks are intended to be modeled to 18,000 feet AGL. If a radar track does not reach 18,000 feet AGL in altitude, then the radar track endpoint was determined at its' intersection with the 18,000 Foot Supplemental Study Area (described subsequently). If a radar track does not reach 18,000 feet AGL or intersect the 18,000 Foot Supplemental Study Area, then the radar track's endpoint was determined such that the cruise portion of the flight is modeled as much as possible. The location of each radar track's endpoint was calculated and recorded.

The 18,000 Foot Supplemental Study Area is constructed by determining the spatial location of where departing and arriving radar tracks cross 18,000 feet altitude AGL. Anomalous and/or irregular radar tracks are discarded from the construction of this boundary so that potential distortion of the lateral boundary can be avoided, and the boundary is kept to a reasonable size.

A backbone's endpoint location (and that of all associated sub-tracks) is determined to be the endpoint of the radar track that is furthest from the airport of the radar tracks composing that bundle. For flight tracks that reach 18,000 feet AGL, calculating the location of a backbone's endpoint in this manner ensures the backbone endpoint's altitude reaches at least 18,000 feet AGL. Due to variety in endpoint location of the radar tracks that compose a bundle, the backbone endpoint's altitude is often determined to be higher than 18,000 feet AGL. For a small number of cases, due to complex track geometry, a backbone's endpoint can exist outside the 18,000 Foot Supplemental Study Area. Also note that this methodology can also result in flight tracks being modeled beyond the Air Defense Identification Zone (ADIZ)<sup>14</sup>. Note, however, that the lengths of the backbone tracks are preserved (either by preserving its total distance for departures, or relative straight-line distance from the airport for arrivals) in the modeling of Proposed Action tracks to ensure equity in track length when comparisons

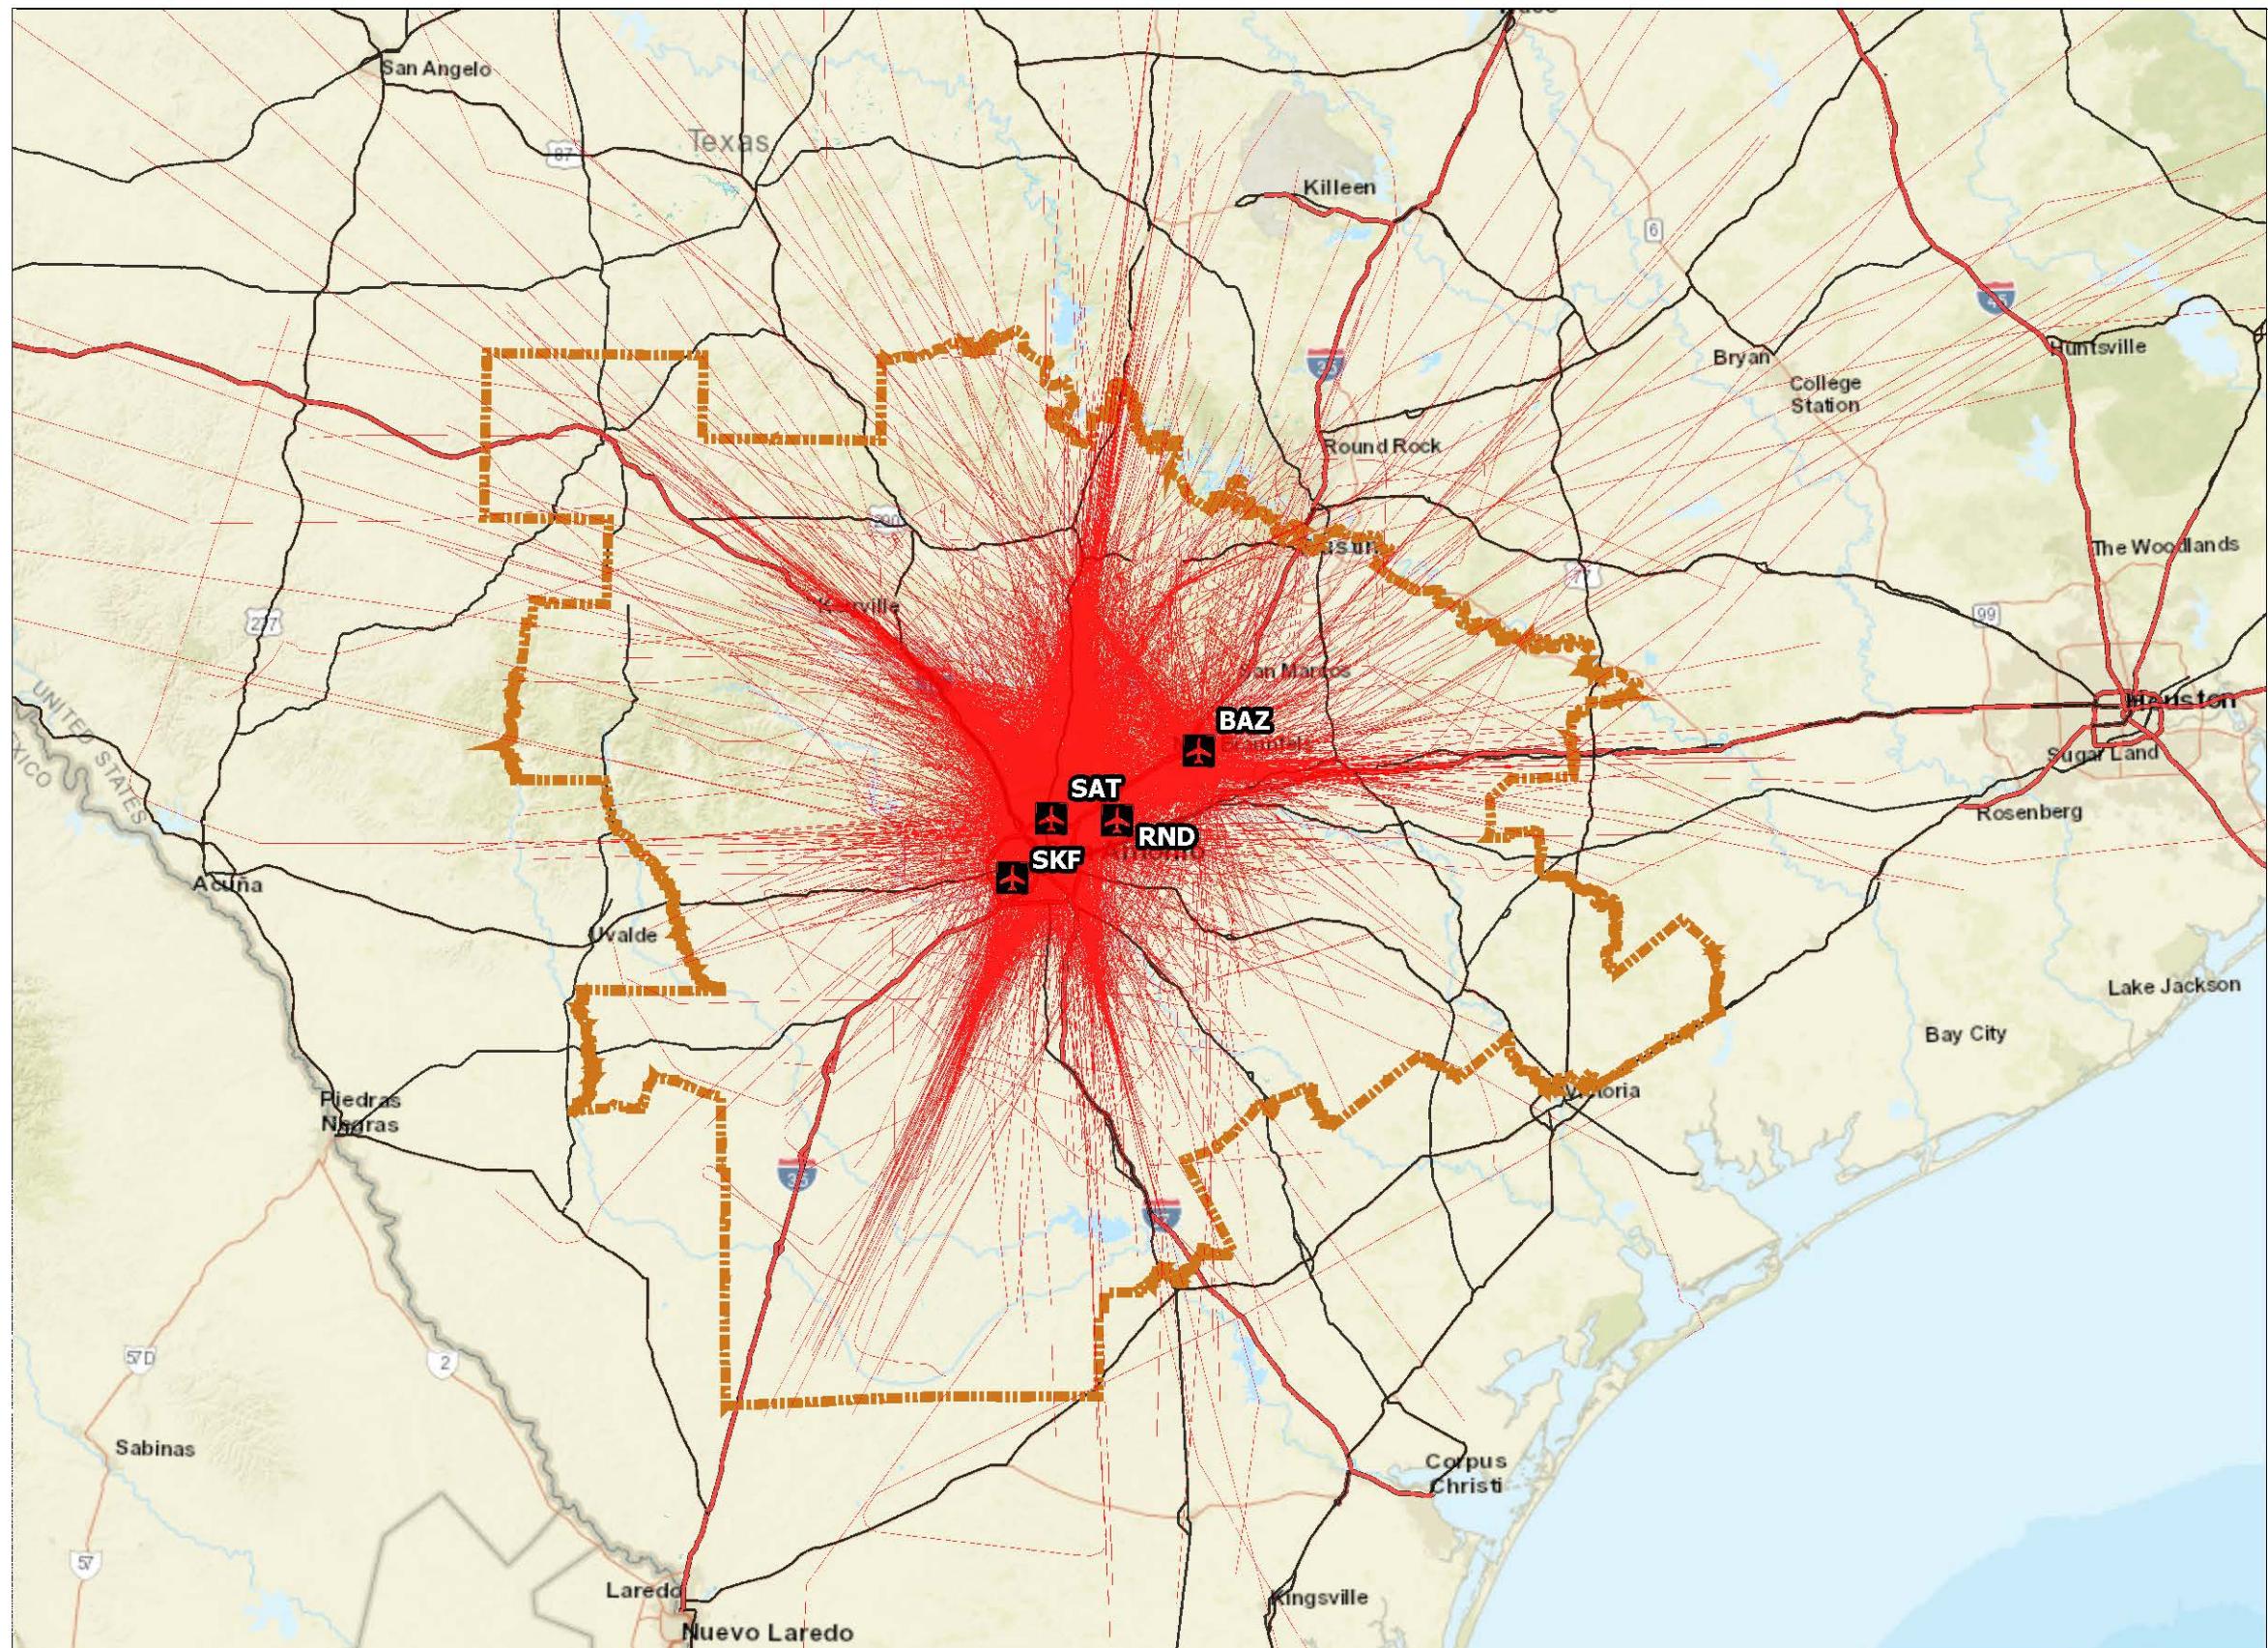

14 FAA. [https://www.faa.gov/air\\_traffic/publications/us\\_restrictions/airspace/#adiz](https://www.faa.gov/air_traffic/publications/us_restrictions/airspace/#adiz), Accessed September 2022.

are made across scenarios. The backbones (and all associated sub-tracks) serve as inputs into AEDT, which then calculates noise and emissions based on entire input tracks as described above.

Radar data analysis resulted in the development of 4,127 unique AEDT and NOISEMAP departure tracks for AEDT model input (backbones and sub-tracks). **Exhibit 5** presents the Draft EA AEDT and NOISEMAP departure tracks used in the modeling of 2021/2022 Existing Conditions scenario. The analysis also resulted in the development of 5,663 AEDT and NOISEMAP unique arrival tracks (backbones and sub-tracks). **Exhibit 6** presents the Draft EA AEDT and NOISEMAP arrival tracks used in the modeling of 2021/2022 Existing Conditions scenario.

A majority of the routing for No Action airspace procedures in 2023 and 2028 is anticipated to be identical to the routing in the 2021/2022 Existing Conditions scenario. This assumption excludes the addition of previously developed procedures identified as having independent utility and separately analyzed for environmental effects (Cumulative Impacts in Section 5.10 of the EA). As a result, the model tracks created from 2021/2022 Existing Conditions scenario, including these procedures, were used directly in the modeling of No Action.

**SAN ANTONIO AIRSPACE MODERNIZATION PROJECT**

**SAT Airspace Modernization EA AEDT Arrival Tracks - Existing Conditions**

DRAFT

October 2022

**Exhibit 6**

**THIS PAGE INTENTIONALLY LEFT BLANK**

### 3.1.11 Flight Track Assignments

The final step in developing the flight track input data for the AEDT model is the assignment of aircraft to specific flight tracks. The flight data associated with each radar data bundle was retained as an attribute of each AEDT backbone and sub-track. This data included aircraft type, time of day (day or night), and flight origin or destination. The resulting backbones and sub-tracks are used as the AEDT model input tracks. As a result, each AEDT model input track does not necessarily represent one flight operation; it could represent many operations or a small fraction of an operation.

### 3.1.12 User-Defined Profiles

A user-defined profile was required to model arrivals for the MD11GE aircraft type. AEDT 3d does not have procedure step profiles for arrivals for this aircraft type. Thus, a user-defined profile was created based on the approach procedure steps from a DC1030 aircraft in the model. Details regarding the creation of these user-defined profiles can also be found in **Supplement 2**.

### 3.1.13 Receptor Sets

Receptors are locations in AEDT where noise is calculated. Receptors can be grouped together into receptor sets. The first receptor set contains 46,954 receptors based on population data to represent 3,574,741 people (see **Section 2.3.1** for details). The second receptor set contains 46,453 receptors<sup>15</sup> representing Section 4(f), historic, cultural, and Department of Interior locations deemed noise sensitive (see **Section 2.3.2** for details). The third receptor set contains 118,489 receptors that have been regularly spaced at 0.5 NM apart to capture the noise level changes in any areas that were not covered by the population centroid and Section 4(f) properties and resources grids (see **Section 2.3.3** for details). The fourth receptor set contains 198 receptors to represent noise sensitive land use area in regions of high noise levels about the Study Airports (see **Section 2.3.4** for details).

Noise values for Existing Conditions, No Action, and Proposed Action scenarios for all of the aforementioned receptor sets can be found in Supplements 3 to 6 of this report. In addition, the receptor points that intersect the SNIDR Supplemental Study Area (see **Section 2.2.3**) are presented in Supplement 7 in **Table S7.1**. Note that all noise values presented are calculated by combining noise results from AEDT and NOISEMAP (see **Section 4.3** for details).

## 3.2 NOISEMAP

Noise modeling in NOISEMAP requires several types of input data including airport/runway locations, local environmental variables, operational levels, day/night distributions, runway usage, fleet mix, climb/descent profiles, flight track definitions and assignment, and receptor sets. Details of the NOISEMAP input data for the Draft EA are discussed below.

### 3.2.1 Model Background

NOISEMAP is a suite of aircraft noise models developed by the US Air Force, which serves as the lead Department of Defense (DoD) agency for aircraft noise modeling of air bases. NOISEMAP contains computational modules that accept data and estimate noise levels caused by aircraft events at many points on the ground in the airbase vicinity. Unlike AEDT, NOISEMAP does not provide fuel burn results, thus does not contribute to air quality results. Moreover, the primary output of NOISEMAP are noise contours near an airfield, and not

<sup>15</sup> This count includes receptors with identical georeferences because a point can represent the same property from multiple sources.

necessarily noise values at particular census points. **Section 4.3** discusses how the noise results from the NOISEMAP models were combined with the AEDT results.

### **3.2.2 Leveraging Existing Reports & Models**

Based on consultations with the FAA, it was decided that the noise modeling of RND and SKF for the Draft EA should leverage existing NOISEMAP models. These models were developed from recent Air Installations Compatible Use Zones (AICUZ) studies performed by the U.S. Air Force Civil Engineer Center. The FAA provided two studies, with a NOISEMAP model and report for each study. The first study was focused on RND with an accompanying report titled “Final Joint Base San Antonio-Lackland, Texas Air Installations Compatible Use Zones (AICUZ) Study.”<sup>16</sup> The second study focused on SKF with an accompanying report titled “Joint Base San Antonio-Randolph and Seguin Auxiliary Airfield, Texas: Air Installations Compatible Use Zones (AICUZ) Study Final.”<sup>17</sup> Information and data within these reports supported assumptions and decisions made during the modeling process. In addition, the *Final Environmental Impact Statement: T-7A Recapitalization at Joint Base San Antonio, Texas* (henceforth referred to T-7A Recapitalization EIS),<sup>18</sup> served as a resource for T-38C and T-7A operation levels for the modeled scenarios (see **Section 2.1**).

NOISEMAP models were acquired and used as a starting point to model airspace operations and noise at RND and SKF. Much of the input data and information present in the models remained unchanged during the modeling process (e.g., runway and weather data). It was assumed that the data within the models was correct and accurate. Adjustments were made to the existing models to accurately represent the San Antonio Airspace Modernization Project (e.g., flight tracks, flight profiles, fleet mix). Additionally, adjustments were made to the NOISEMAP models to more closely align with AEDT modeling.

### **3.2.3 Airport and Runway Data**

**Table 9** identifies the airports and runway end names modeled. In total, two airports within the General Study Area were evaluated. All runways at these airports were assumed to be available for traffic assignments in NOISEMAP.

<sup>18</sup> Department of the Air Force, *Final Environmental Impact Statement for T-7A Recapitalization at Joint Base San Antonio, Texas*, February 2022

**Table 9 Study Airport Details - NOISEMAP**

| Airport Name                     | Code | Location              | Runway End Names <sup>1</sup> |
|----------------------------------|------|-----------------------|-------------------------------|
| Randolph Air Force Base Airfield | RND  | Universal City, Texas | 15L, 15R, 33R, 33L            |
| Kelly Field                      | SKF  | San Antonio, Texas    | 16,34                         |

<sup>1</sup> A runway can be used in both directions but is named in each direction separately. Runway number is based on the magnetic direction of the runway (e.g., Runway 09 points to the east direction). The two numbers on either side always differ by 180 degrees. If there is more than one runway pointing in the same direction, each runway number includes an L, C, or R at the end. This is based on a runway's position relative to others in the same direction – left, center, or right.

Prepared by: ATAC Corporation, August 2022.

### 3.2.4 Local Environmental Variables

The NOISEMAP models utilized the same terrain data used in AEDT modeling (see **Section 3.1.3**), incorporated from the USGS 1-degree NED.<sup>19</sup> As a result, input terrain data is consistent between the NOISEMAP and AEDT models.

Both of the NOISEMAP models retained weather settings that were used for the AICUZ studies, which were typical local April conditions. For RND, the modeled temperature was 69°F, the humidity was 66.5% and pressure was 29.92 in Hg. SKF was modeled with a temperature of 71°F, a humidity of 67.5%, and a pressure of 29.21 in Hg.

### 3.2.5 Operation Levels and Day/Night Distribution

The 2021/2022 aircraft operations were developed from information contained in the NOISEMAP AICUZ models in combination with projected future basing for T-38C and T-7A aircraft taken from the T-7A Recapitalization EIS.

EAs that primarily focus on airspace changes to Standard Instrument Departures (SIDs), Standard Terminal Arrivals (STARs), and Standard Instrument Approach Procedures (SIAPs), such as this Draft EA, only model Instrument Flight Rules (IFR) itinerant flights. In contrast, AICUZ studies focus on compatible land use near the airport, within a 65 dB noise contour. To match the AEDT inputs and be consistent with the airspace-focused modeling, the following steps were taken to determine 2021/2022 AAD flight operations:

1. 2021/2022 T-38C and T-7A operations were calculated by interpolating between the 2017 and 2023 years listed in the EIS (refer to Appendix H: *Flight Schedules Tech Report*)
2. The 2021/2022 calculation was used to scale T-38C and T-7A operations in the RND and SKF AICUZ models
3. Closed patterns were removed from the models, to match the AEDT inputs and be consistent with the airspace-focused modeling
4. Auxiliary field (Seguin Airfield) and static run-up operations were excluded to match the AEDT methodology
5. Helicopter operations were reviewed, determined to have insignificantly low counts and unlikely to utilize current or future SIDs/STARs/SIAPs, and excluded

Note that all other aircraft operations remained unchanged.

<sup>19</sup> U.S. Department of the Interior, U.S. Geological Survey, National Elevation Dataset, (<http://ned.usgs.gov/>).

As a result of the Department of the Air Force (DAF) recapitalization of T-7A aircraft, it was necessary to model different levels of T-38C and T-7A aircraft for the three years when noise was modeled (2021/2022 Existing Conditions, 2023 No Action and Proposed Action, and 2028 No Action and Proposed Action). Operations for T-38C and T-7A aircraft at RND and SKF were based on the T-7A Recapitalization EIS. Flight operations for all other aircraft types in the AICUZ NOISEMAP models of RND and SKF were kept the same for all scenarios modeled for this EA.

**Table 10** presents the aircraft operation totals modeled for the Draft EA.

**Table 10 Modeled Average Annual Day Aircraft Operation Totals**

| Airport | Existing Conditions<br>(03/2021 – 02/2022) |       | 2023  |       | 2028  |       |
|---------|--|-------|-------|-------|-------|-------|
|         | Day  | Night | Day   | Night | Day   | Night |
| RND     | 251.4                                      | 0.2   | 259.4 | 0.3   | 255.5 | 4.8   |
| SKF     | 44.7                                       | 2.3   | 44.7  | 2.4   | 46.3  | 3.0   |

Prepared by: ATAC Corporation, August 2022.

### 3.2.6 Runway Use

The frequency with which aircraft utilize a runway involves a variety of factors including, but not limited to:

- Airfield environment (layout, lights, runway length)
- Direction of prevailing winds
- Location of natural terrain features (rivers, lakes, mountains, and other features);
- Wildlife activity
- Number of aircraft in the pattern and/or preference of a runway for the purpose of safety and noise abatement

Installation operations, control tower personnel, and the Supervisor of Flying establish the runway in use. Aviation planners adjust the pattern procedures accordingly to maximize air traffic flow efficiency.

Per the *Final Joint Base San Antonio-Lackland, Texas Air Installations Compatible Use Zones (AICUZ) Study* from October 2019, Kelly Field utilizes Runway 16 (arriving from the north and/or departing to the south) 80% of the time, and Runway 34 (arriving from the south and/or departing to the north) the remaining 20%.

The *Joint Base San Antonio-Randolph and Seguin Auxiliary Airfield, Texas: Air Installations Compatible Use Zones (AICUZ) Study Final*, from 2017 defined the following runway usage by aircraft types:

- Predominant runway usage at Randolph Air Force Base Airfield occurs on Runway 15L for T-1 and T-38 training (80 to 85 percent), with the exception of T-38 Depot training departures, which occur on Runway 15R (83 percent)
- The predominant runway used for T-6 is Runway 15R (80 percent)

- The remaining runway use is divided between Runway 33R (14 to 20 percent for T-1 and T-38) and Runway 33L (20 percent for T-6 and 14 percent for T-38 Depot departure)
- Transient flight runway usages are split between Runway 15L (85 percent) and Runway 33R (15 percent)

**Tables 11 and 12** present the runway utilization percentages for RND and SKF. Operations were not moved between runways between No Action and Proposed Action; therefore each 2023 and 2028 are each only presented once.

**Table 11 RND Runway Use Percentages – Proposed Action and No Action**

| Year         | Runway | Annual Day Operations | Annual Night Operations |
|--------------|--------|-----------------------|-------------------------|
| 2023         | 15L    | 58%                   | 83%                     |
|              | 15R    | 25%                   | 1%                      |
|              | 33L    | 6%                    | 0%                      |
|              | 33R    | 11%                   | 16%                     |
| <b>Total</b> |        | <b>100%</b>           | <b>100%</b>             |
| 2028         | 15L    | 57%                   | 83%                     |
|              | 15R    | 25%                   | 1%                      |
|              | 33L    | 6%                    | 0%                      |
|              | 33R    | 11%                   | 16%                     |
| <b>Total</b> |        | <b>100%</b>           | <b>100%</b>             |

### 3.2.7 Aircraft Fleet Mix

Fleet mix and operation counts for the RND and SKF NOISEMAP models were taken directly from the original AICUZ studies with the exception of the T-38, T-7A, and helicopters which were removed. Additional details for RND and SKF fleet mix and operation counts are discussed in Appendix H: *Flight Schedules Technical Report*.

### 3.2.8 Aircraft Climb/Descent Profiles

Flight profiles within the NOISEMAP models were used as-is, as much as possible, beginning from the two AICUZ models. In order to reflect airspace changes due to the proposed STARs/SIDs, as well as be more consistent with the AEDT modeling for the other study airports, flight profiles were adjusted from the initial set. Flight profiles were adjusted by lengthening flight tracks to either reach the General Study Area Boundary or 18,000 ft AGL (see **Section 3.2.9**). Departure flight profiles were adjusted to continue existing climb segments up to 18,000 ft AGL, or a cruise segment to the study boundary. Similarly, arrival profiles were adjusted to maintain existing descent rates from 18,000 ft AGL, or a lower cruise segment to the study boundary.

Flight profiles were adjusted so that climb angles, power settings, and speeds were consistent with values in the original NOISEMAP models. For Proposed Action, flight profiles were adjusted to follow altitude restrictions defined for each SID/STAR. In the cases where this process introduced unrealistic trajectories, the profiles were adjusted as needed.

T-7A profiles were added to the SKF model, as they did not exist in the AICUZ model as it was received. The new profiles were based on existing T-38 profiles, and their operations were scaled to match the planned total aircraft operations in the T-7A Recapitalization EIS.

### 3.2.9 Flight Track Definitions

The AICUZ NOISEMAP model flight tracks were used as starting point and modified as needed. To remain consistent with AEDT inputs and cover the required 4(f) criteria, flight tracks from the original model were extended to reach 18,000 feet AGL or to the General Study Area Boundary, as appropriate. The maximum altitude for each modeled track was determined by measuring the average maximum altitude within each flow of the radar data.

Additionally, tracks were modified laterally as needed to capture existing traffic flows in the historical radar data. In some cases, additional tracks were defined to represent traffic flows found in the radar data which were not in the AICUZ models.

For Proposed Action, tracks were created and/or moved to represent the proposed SIDs and STARs.

**Table 13** presents the number of tracks with operations in each of the NOISEMAP models. Note that Existing Conditions and No Action had the same tracks and profiles, and the only change was number of operations.

**Table 13 NOISEMAP Flight Track Counts**

| Airport Code | Original AICUZ Models |          | Existing Conditions/<br>No Action |          | Proposed Action |          |
|--------------|-----------------------|----------|-----------------------------------|----------|-----------------|----------|
|              | Airport               | Arrivals | Departures                        | Arrivals | Departures      | Arrivals |
| RND          | 62                    | 28       | 135                               | 46       | 143             | 46       |
| SKF          | 47                    | 13       | 64                                | 19       | 82              | 24       |

Prepared by: ATAC Corporation, August 2022.

### 3.2.10 Flight Track Assignments

The flight operations assigned to the modeled tracks were taken directly from the existing AICUZ NOISEMAP models. In some cases, it was necessary to create additional flight tracks to represent observed traffic flows in existing radar data that were not represented in the existing AICUZ NOISEMAP models (for Existing Conditions and No Action). For these cases, operations from existing nearby tracks were transferred among the new tracks to match the proportion of the observed traffic in each area.

### 3.2.11 Receptor Sets

The referenced AICUZ NOISEMAP models included receptor sets that were sufficient to capture noise contours near the airport. To provide noise measurements that capture airspace changes, an additional receptor set covering the General Study Area Boundary and 18,000 Foot Supplemental Study Area were created. This receptor set was created as an equally spaced cartesian grid of 2,500 points with a 0.1 NM resolution.

Additionally, in order to capture the noise impacts of RND operations on SKF and noise impacts of SKF operations on RND, the receptor sets from each model were input into the other.

The existing NOISEMAP grid pattern and density from the respective SKF and RND studies were used to capture areas nearest each airfield. For RND, the cartesian grid was input with 300 by 300 points spaced 750 feet apart from each other. For SKF, the cartesian grid was input with 101 points in an East-West direction and 151 in a North-South direction, with these points spaced 1,000 feet apart.

As defined above, the “Large” cartesian grid was input with 2,500 by 2,500 points spaced 607 feet (0.1NM) apart.

NOISEMAP uses the Noise Model Grid Format (NMGF) standard format for grid files. This allows for post-processing of multiple noise model results at the same location and for the combining model outputs to produce an overall grid of noise results.

NMPlot is part of the BaseOps toolset and can combine grid files with different grid spacing and spatial coverage. NMPlot was used to merge NOISEMAP grids and then combine them with AEDT grids.

First, the NOISEMAP grids were merged into a single grid using NMPlot. This combined NOISEMAP grid was then combined with the AEDT grid, again using NMPlot. Further information on how the output of the NOISEMAP receptor set was combined with output of the AEDT receptor set can be found in **Section 4.3.1**.

**THIS PAGE INTENTIONALLY LEFT BLANK**

## 4 Noise Modeling Procedures

### 4.1 AEDT

AEDT processes flight track and operation data following several major steps: data integration and quality control, calculation of flight dynamics (i.e., thrust and speed), noise exposure computation, annualization of noise exposures, change of exposure analysis, and report generation. Key aspects of this process are discussed below.

#### 4.1.1 Model Input

The input for the AEDT modeling effort was developed in accordance with the data, sources, and methodologies presented in the previous sections. The input files for the Proposed Action and No Action vary due to the differences in procedures under each alternative.

#### 4.1.2 Data Integrity Checks

Before any AEDT modeling is executed, data integrity checks are performed to ensure the model does not reject the inputs being provided. The following checks were made in the Draft EA noise analysis:

- Flight trajectories (flight tracks) were adjusted so that no arrival trajectories contained any ascending segments and no departure trajectories contained any descending segments.
- Flight trajectories were adjusted so that unrealistic turn angles were not present in the input trajectory.
- Runway end coordinates for flight trajectories were verified to be accurate and corrected if necessary.
- Input profiles were checked against those available in AEDT system databases to ensure that all profiles were available to be modeled.
- If necessary, aircraft profile data was adjusted to ensure compliance with aircraft profile approvals by the FAA.
- Operations counts were cross-referenced before and after input into the model to ensure that all operations were successfully imported into the model.

After AEDT modeling was completed, other data integrity checks were performed to verify that all operations that were intended to be modeled were successfully modeled. The following checks were made:

- Each operation was verified to have its performance calculations successfully modeled.
- All intended noise exposure and emissions calculations were successfully performed.

#### 4.1.3 Extract Results

After all noise calculations were complete, AEDT noise data was recorded for all scenarios at each receptor location. These results were extracted, formatted, and prepared to be combined with NOISEMAP output data for impact analysis (see **Section 4.3**).

### 4.2 NOISEMAP

NOISEMAP is a suite of noise models for generating noise exposure contours in various metrics around US military bases. Noise and performance data files for military and civilian

aircraft are included in the program. BASEOPS is a Windows graphical user interface that guides the user through creation of a noise case. NMPLT is the analysis tool which allows the user to view and modify output from a NOISEMAP model.

For the Draft EA, NMAP, the US Department of Defense's model of aircraft flight and run-up noise near air bases was the noise model used to generate noise data.

### **4.2.1 Model Input**

The input for the NOISEMAP modeling effort was developed in accordance with the data, sources, and methodologies presented in the previous sections. The input files for the Proposed Action and No Action vary due to the differences in procedures under each alternative.

### **4.2.2 Data Integrity Checks**

NOISEMAP has multiple built-in data integrity checks, which are automatically assessed any time a case is attempted to be run. These include but are not limited to: checking that every profile is assigned to a flight track, ensuring that every profile length is no longer than its assigned track, and ensuring that each track is assigned to a runway.

Additionally, the following checks were made in the Draft EA noise analysis:

- Flight trajectories were adjusted so that unrealistic climb and descent angles were not present in the input trajectory
- Operations counts were cross-referenced before and after input into the model to ensure that all operations were successfully imported into the model

### **4.2.3 Extract Results**

After all noise calculations were complete, NOISEMAP noise data was recorded for all scenarios at each receptor location. These results were extracted, formatted, and prepared to be combined with AEDT output data for impact analysis (see **Section 4.3**).

## **4.3 Integrate Output Data for Impact Analysis**

Noise output data from each model was integrated to produce a final grid of noise values for each scenario. Each scenario's noise values were compared using the impact criteria presented in **Section 1.1**.

### **4.3.1 Merging & Combining**

Merging refers to creating a grid with noise values containing all data points from two or more existing grids. The resulting merged grid is equal to the union of the original grids. This process can be performed as the noise values represent the same noise metric (DNL) and are calculated as a result of the same set of flight tracks and operations.

Combining refers to the creation of a new grid by performing a mathematical operation on the data points in two existing grids. The mathematical operation is an addition of noise decibels, specifically DNL values for this effort.

The following steps were taken to merge and combine noise results for each of the five scenarios (see **Section 2.1**):

1. Merge noise results from all receptor sets from RND NOISEMAP model
2. Merge noise results from all receptor sets from SKF NOISEMAP model
3. Combine merged noise results from RND and SKF NOISEMAP models

4. Merge noise results from all receptor sets from AEDT model
5. Combine the combined noise results from NOISEMAP models (Step 3) with merged noise results from AEDT model (Step 4)

The final result is a grid of noise values that reflects noise from all receptor sets and runs from both AEDT and NOISEMAP models for all four study airports for each scenario.

#### **4.3.2 Determine Noise Impacts**

After all noise calculations were complete, noise impacts were determined by locating and categorizing changes in noise values between scenarios. Using FAA threshold criteria (significant impact and reportable noise change thresholds described in **Section 1.1, Noise Impact Criteria**), maps depicting zones of various types of change in annualized DNL noise exposure between scenarios were produced for the entire General Study Area.

**THIS PAGE INTENTIONALLY LEFT BLANK**

## 5 Analysis

The results from the five scenarios outlined in **Section 2.1** were analyzed. Noise impact results were tabulated based on the potential implementation of the Proposed Action compared to the No Action at the previously described grid points.

The following sections present both a summary of the noise model input modifications made to model the Proposed Action and the results of the noise analysis for each scenario.

### 5.1 Existing Conditions

The 2021/2022 Existing Conditions Scenario modeled in AEDT and NOISEMAP represent flight operations at the study airports from March 1, 2021 to February 28, 2022. During this time period, a total of 14 procedures were found across all study airports. The 14 procedures include eight Standard Terminal Arrival (STAR) procedures (BELLR, BRAUN, CENTERPOINT, HTOWN, LEMIG, MARCS, STONEWALL, TEJAS) and six Standard Instrument Departures (SIDs) (ALAMO, ALISS, BOWIE, LEJON, MILET, THREE RIVERS). Versions of these airspace procedures were previously evaluated through separate environmental analysis documentation.

### 5.2 No Action

For No Action conditions, no independent utilities were identified. Therefore, the only changes to the Existing Conditions scenarios to represent the No Action scenarios was to apply fleet mix and forecast adjustments. These adjustments are discussed in detail in Appendix H: *Flight Schedules Technical Report*.

Aside from the adjustments stated above, the 2023 and 2028 No Action scenarios model inputs were the same as the 2021/2022 Existing Conditions scenario.

### 5.3 Proposed Action

The Proposed Action consists of several air traffic procedure modifications as discussed in the EA, Chapter 3, *Alternatives*. Those modifications were implemented in the noise modeling through adjustments to the flight track routing at the Study Airports, or developed as new tracks. Consultations with subject matter experts confirmed assumptions that were made with regards to the track adjustments. Utilization percentages of new Standard Instrument Arrival Procedures (SIAPs) at SAT were determined based on observations of operations in the flight data acquired to model the Existing Conditions Scenario. The flight track adjustments are further discussed in the following sections.

Since the Proposed Action does not involve changes that are considered capacity enhancements or any actions that would induce growth in operations, operation levels, fleet mix, and day/night distribution, inputs were the same as for No Action for both 2023 and 2028. Environmental variables (i.e., temperature, humidity, barometric pressure, and headwind) were the same among Existing Conditions, No Action, and Proposed Action. The following sections describe changes related to tracks developed for the Proposed Action.

Proposed Action changes are aimed to improve airspace safety and efficiency. Proposed changes to existing procedures mitigate possible route conflicts and reduce the number and length of level-offs that aircraft are instructed to fly. Moreover, new procedures will enhance pilot-air traffic control communications by formalizing routes that are frequently used. These new routes are largely Area Navigation (RNAV) (GPS-based) or Required Navigational Performance (RNP) procedures that allow for greater control of aircraft in the airspace. This

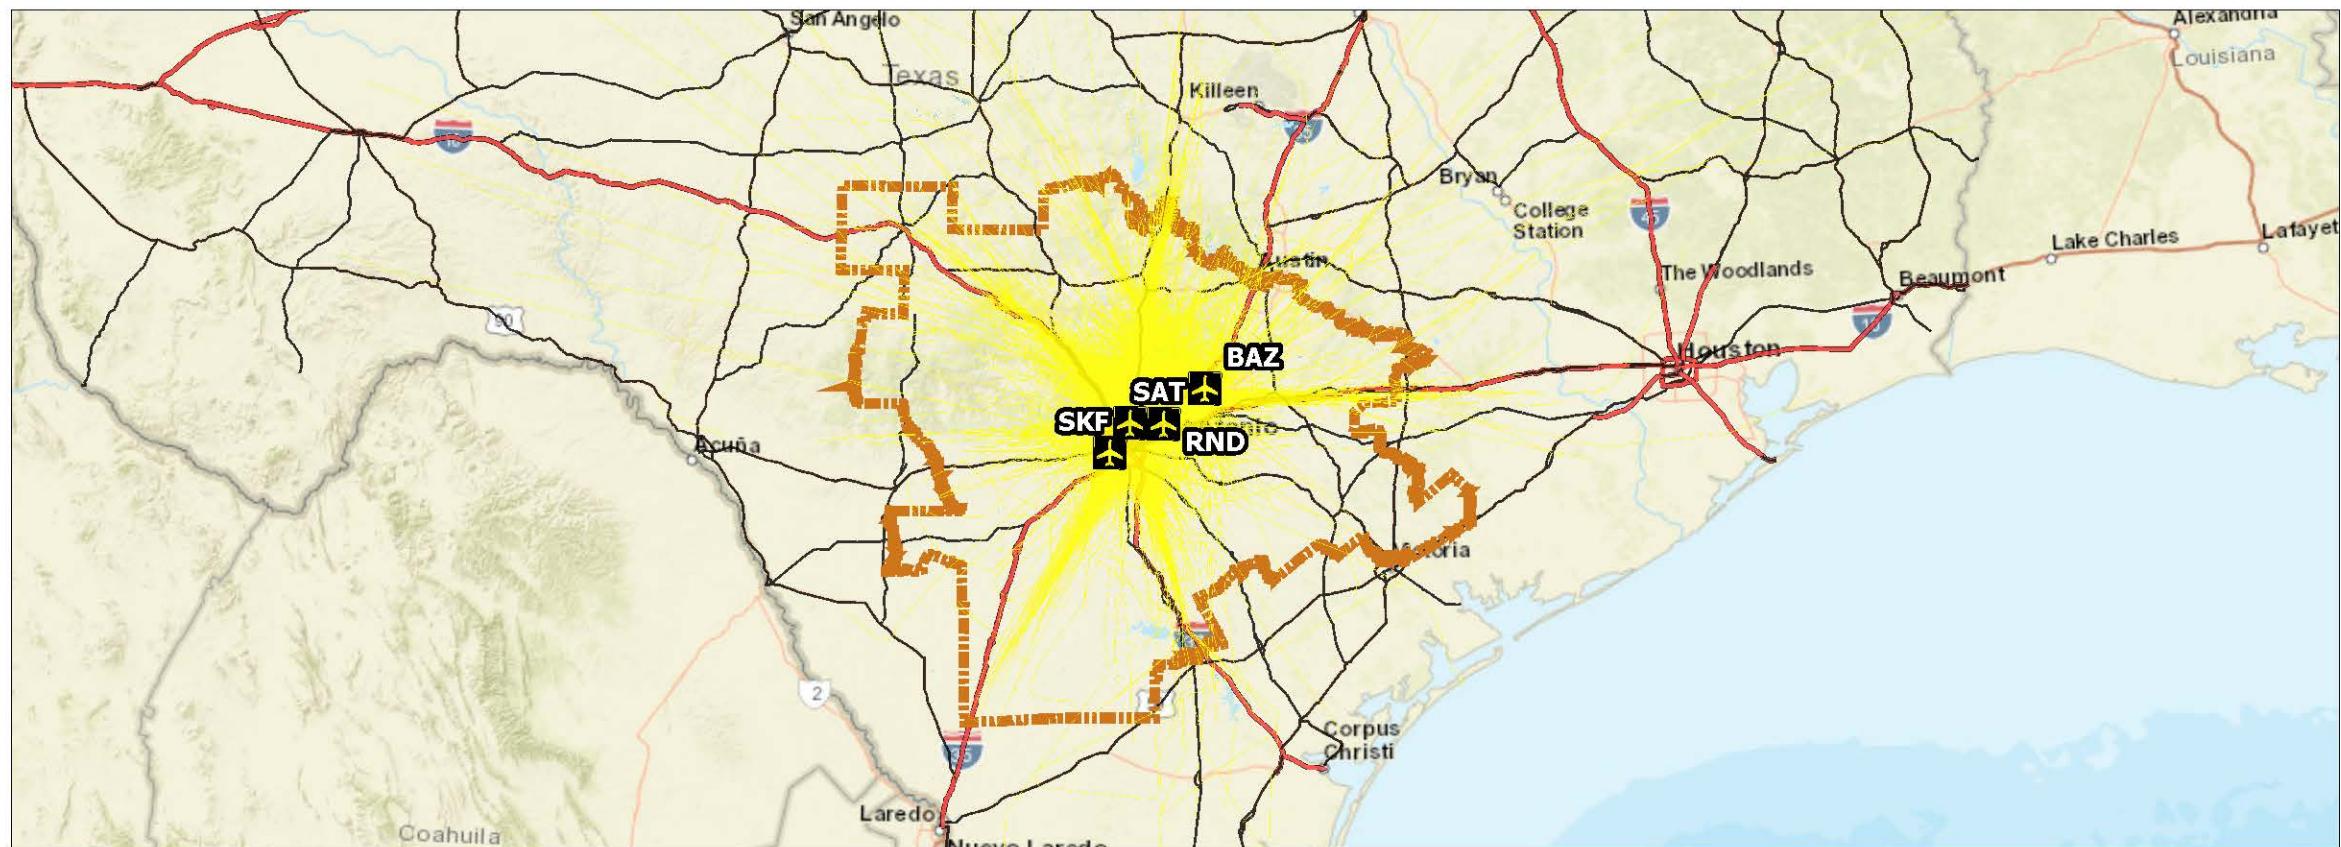

represents a greater use of standardized procedures that increase routing predictability, flexibility, and traffic segregation.

### **5.3.1 Departures**

The Proposed Action changes constitute a general trend away from radar vector operational ATC procedures for portions of the departure trajectory and toward increased use of Area Navigation (RNAV) Standard Instrument Departure (SID) procedures. The changes between Proposed Action and No Action routing for AEDT and NOISEMAP departure tracks from the Study Airports are shown in **Exhibit 7**. Proposed Action routes are depicted in yellow, and No Action routes are depicted in blue.

### **5.3.2 Arrivals**

The Proposed Action changes constitute a general trend away from radar vector operational ATC procedures for portions of the arrival trajectory and toward increased use of Area Navigation (RNAV) Standard Terminal Arrival (STAR) procedures. Furthermore, there is a general trend to update and implement new RNP and GPS-based SIAPs. The changes between Proposed Action and No Action routing for AEDT and NOISEMAP arrival tracks to the Study Airports are shown in **Exhibit 8**. Proposed Action routes are depicted in orange, and No Action routes are depicted in purple.

## 5.4 Impact Analysis Results

This section presents the results of the impact analysis between the Proposed Action and No Action scenarios. The summary of results includes results from the 2023 and 2028 scenarios across 2020 US Census Population Centroids, 0.5 NM Evenly Spaced Grid Points, and 4(f) resource unique points.

For 2023, no significant noise (+1.5 DNL dB resulting in 65 DNL dB or higher) was identified. 11 Census Centroid receptor points representing 573 persons were identified in the +5.0 dB resulting in a value of 45-60 DNL dB. Six 0.5 NM evenly spaced grid receptor points were identified in the +5.0 dB resulting in a value of 45-60 DNL dB. Finally, six 4(f) receptor points representing 11 named resources were identified in the +5.0 dB resulting in a value of 45-60 DNL dB.

For 2028, no significant noise (+1.5 DNL dB resulting in 65 DNL dB or higher) was identified. Three Census Centroid receptor points representing 100 persons were identified in the +3.0 dB resulting in a value of 60-65 DNL dB. Two 0.5 NM evenly spaced grid receptor points were identified in the +3.0 dB resulting in a value of 60-65 DNL dB. 108 Census Centroid receptor points representing 8,068 persons were identified in the +5.0 dB resulting in a value of 45-60 DNL dB. 130 0.5 NM evenly spaced grid receptor points were identified in the +5.0 dB resulting in a value of 45-60 DNL dB. Finally, 19 4(f) receptor points representing 24 named resources were identified in the +5.0 dB resulting in a value of 45-60 DNL dB.

### 5.4.1 Population Data

**Table 14** presents the change in potential population exposed to increased aircraft noise under the Proposed Action for 2023 conditions. The analysis indicates that the Proposed Action would not result in a DNL 1.5 dB increase in areas exposed to DNL of 65 dB and higher, nor would it result in a reportable noise increase of DNL 3.0 dB in areas exposed to DNL 60 dB to 65 dB.

However, the 2023 Proposed Action did result in a reportable noise increase of DNL 5.0 dB in areas exposed to DNL 45 dB to 60 dB. According to census data, a total of 573 people, associated with 11 population centroids, would be impacted by this increase. The population centroids are located in two general areas. The first area is located approximately 12.5 NM east of SAT near the border of Guadalupe and Bexar Counties. The second area is located approximately 10 NM northeast of SAT in Comal County. Details for these population centroids are presented in **Supplement 3** and shown in **Exhibit 9**.

The reportable noise increase is attributable to aircraft departing RND heading north in the 2023 No Action scenario shifting to utilize the YODUH SID in the 2023 Proposed Action scenario.

**Table 14 Change in Potential Population Exposed to Increased Aircraft Noise - 2023**

| DNL Noise Exposure Level Under the Proposed Action | Increase in DNL with the Proposed Action | Population Exposed to Noise that Exceeds the Threshold |
|--|--|--|
| DNL 65 dB and higher                               | DNL 1.5 dB or greater                    | 0  |
| DNL 60 dB to 65 dB                                 | DNL 3.0 dB or greater                    | 0  |
| DNL 45 dB to 60 dB                                 | DNL 5.0 dB or greater                    | 573  |

Source: 2020 U.S. Census (population centroid data), April 2022; ATAC Corporation, AEDT modeling results, August 2022

Prepared By: ATAC Corporation, August 2022.

**Table 15** presents the change in potential population exposed to increased aircraft noise under the Proposed Action for 2028 conditions. The analysis indicates that the Proposed Action would not result in a DNL 1.5 dB increase in areas exposed to DNL of 65 dB and higher.

However, the 2028 Proposed Action did result in reportable noise increases of DNL 3.0 dB in areas exposed to DNL 60 dB to 65 dB. According to census data, a total of 100 people, associated with three population centroids, would be impacted by this increase. The population centroids are located approximately 12.5 NM east of SAT near the border of Guadalupe and Bexar Counties. Details for these population centroids are presented in **Supplement 3** and shown in **Exhibit 10**. These centroids align with modeled departure tracks for flights departing RND using the proposed YODUH SID.

Additionally, the Proposed Action resulted in a reportable noise increase of DNL 5.0 dB in areas exposed to DNL 45 dB to 60 dB. According to census data, a total of 8,068 people, associated with 108 population centroids, would be impacted by this increase. The population centroids are located in five general areas. The first area is located approximately 10 NM northeast of SAT near the border of Bexar and Comal Counties. The second area is located approximately 20 NM north of SAT in Comal and Blanco Counties. The impact points at these first two locations align with modeled departure tracks for flights departing RND using the proposed YODUH SID. The third and fourth areas are located approximately 12 NM north and 17 NM northwest of SAT, respectively. These areas are near the borders of Comal, Bexar, and Kendall counties. These areas align with modeled departure tracks for flights departing RND using the proposed ALISS SID. The fifth area is about 17 NM northwest of SAT in Bexar County and aligns with modeled tracks for flights arriving to SKF using the proposed POPPO STAR.

The reportable noise increase at the aforementioned locations is attributable to aircraft operations utilizing three Proposed Action procedures. The first set of operations that are the likely cause of these noise impacts are aircraft departing RND heading north in the 2028 No Action scenario shifting to utilize the YODUH SID in the 2028 Proposed Action scenario. These operations impact locations to the north and east of SAT. The second set of operations that are a likely cause of noise impacts are aircraft departing RND heading northwest in the 2028 No Action scenario shifting to utilize the ALISS SID in the 2028 Proposed Action scenario. These operations impact locations to the north and northwest of SAT. Finally, arrivals to SKF utilizing the STV arrival procedure in the No Action 2028 Scenario shifting to utilize the POPPO STAR in the Proposed Action 2028 Scenario are the likely cause of the noise impacted locations northwest of SAT.

**Table 15 Change in Potential Population Exposed to Increased Aircraft Noise - 2028**

| DNL Noise Exposure Level Under the Proposed Action | Increase in DNL with the Proposed Action | Population Exposed to Noise that Exceeds the Threshold |
|--|--|--|
| DNL 65 and higher                                  | DNL 1.5 dB or greater                    | 0  |
| DNL 60 to 65                                       | DNL 3.0 dB or greater                    | 100  |
| DNL 45 to 60                                       | DNL 5.0 dB or greater                    | 8,068  |

Prepared By: ATAC Corporation, August 2022.

### 5.4.2 4(f), Historic, and Cultural Resources

For the 4(f), Historic, and Cultural Resources areas in the 2023 scenarios, the analysis indicates that the Proposed Action would not result in a DNL 1.5 dB increase in areas exposed to DNL of 65 dB and higher, nor would it result in a reportable noise increase of DNL 3.0 dB in areas exposed to DNL 60 dB to 65 dB compared with the 2023 No Action scenario. However, the 2023 Proposed Action did result in a reportable noise increase of DNL 5.0 dB in areas exposed to DNL 45 dB to 60 dB. The locations of these 4(f), Historic, and Cultural Resources reportable noise points are in the same two general areas as the noise impacted population centroids found in the 2023 scenarios: one area is approximately 12.5 NM east of SAT near the border of Guadalupe and Bexar Counties; and another approximately 10 NM northeast of SAT in Comal County. These 4(f), Historic, and Cultural Resources areas with reportable noise impacts are shown in **Exhibit 9**. Detailed information for all 4(f), Historic, and Cultural Resources areas is provided in **Supplement 4**.

Similarly, for the 4(f), Historic, and Cultural Resources areas in the 2028 scenarios, the analysis indicates that the Proposed Action would not result in a DNL 1.5 dB increase in areas exposed to DNL of 65 dB and higher, nor would it result in a reportable noise increase DNL 3.0 dB in areas exposed to DNL 60 dB to 65 dB compared with the 2028 No Action scenario. However, the 2028 Proposed Action did result in a reportable noise increase of DNL 5.0 dB in areas exposed to DNL 45 dB to 60 dB. The locations of these 4(f), Historic, and Cultural Resources reportable noise points are in similar areas as the noise impacted population centroids found in the 2028 scenarios. The points are all about 10 to 20 NM north and east of SAT. These 4(f), Historic, and Cultural Resources areas with reportable noise impacts are shown in **Exhibit 10**. Detailed information for all 4(f), Historic, and Cultural Resources areas is provided in **Supplement 4**.

The reportable noise increase in the 2023 Proposed Action scenario is attributable to the use of the YODUH SID from RND departures. For the reportable noise increase in the 2028 Proposed Action scenario, the likely causes are the use of YODUH and ALISS SIDs from RND departures.

### 5.4.3 One-Half Nautical Mile Grid

For the 0.5 NM Grid Point data in both the 2023 and 2028 scenarios, the analysis indicates the Proposed Action would not result in a DNL 1.5 dB increase in areas exposed to DNL of 65 dB and higher. Moreover, the 2023 Proposed Action scenario also did not result in a DNL 3.0 dB increase in areas exposed to DNL 60 dB to 65 dB compared to the 2023 No Action scenario.

However, the 2028 Proposed Action scenario did result in a reportable noise increase of DNL 3.0 dB in areas exposed to DNL 60 dB to 65 dB compared with the 2028 No Action scenario at two grid points. The locations of these grid points are in similar areas as the noise impacted population centroids found in the 2028 scenarios.

In addition, for the 2023 scenarios, six grid points would experience a greater than DNL 5 dB increase in areas exposed to DNL between 45 dB and 60 dB in the Proposed Action scenario. The locations of these grid points are in similar areas as the noise impacted population centroids found in the 2023 scenarios. For the 2028 scenarios, 130 grid points would experience a greater than DNL 5 dB increase in areas exposed to DNL between 45 dB and 60 dB in the Proposed Action scenario. The locations of these grid points are in similar areas as the noise impacted population centroids found in the 2028 scenarios. The 0.5 NM reportable noise impact points for the 2023 and 2028 scenarios are shown in **Exhibits 9** and **10**, respectively. Detailed information for all 0.5 NM Grid points is provided in **Supplement 5**.

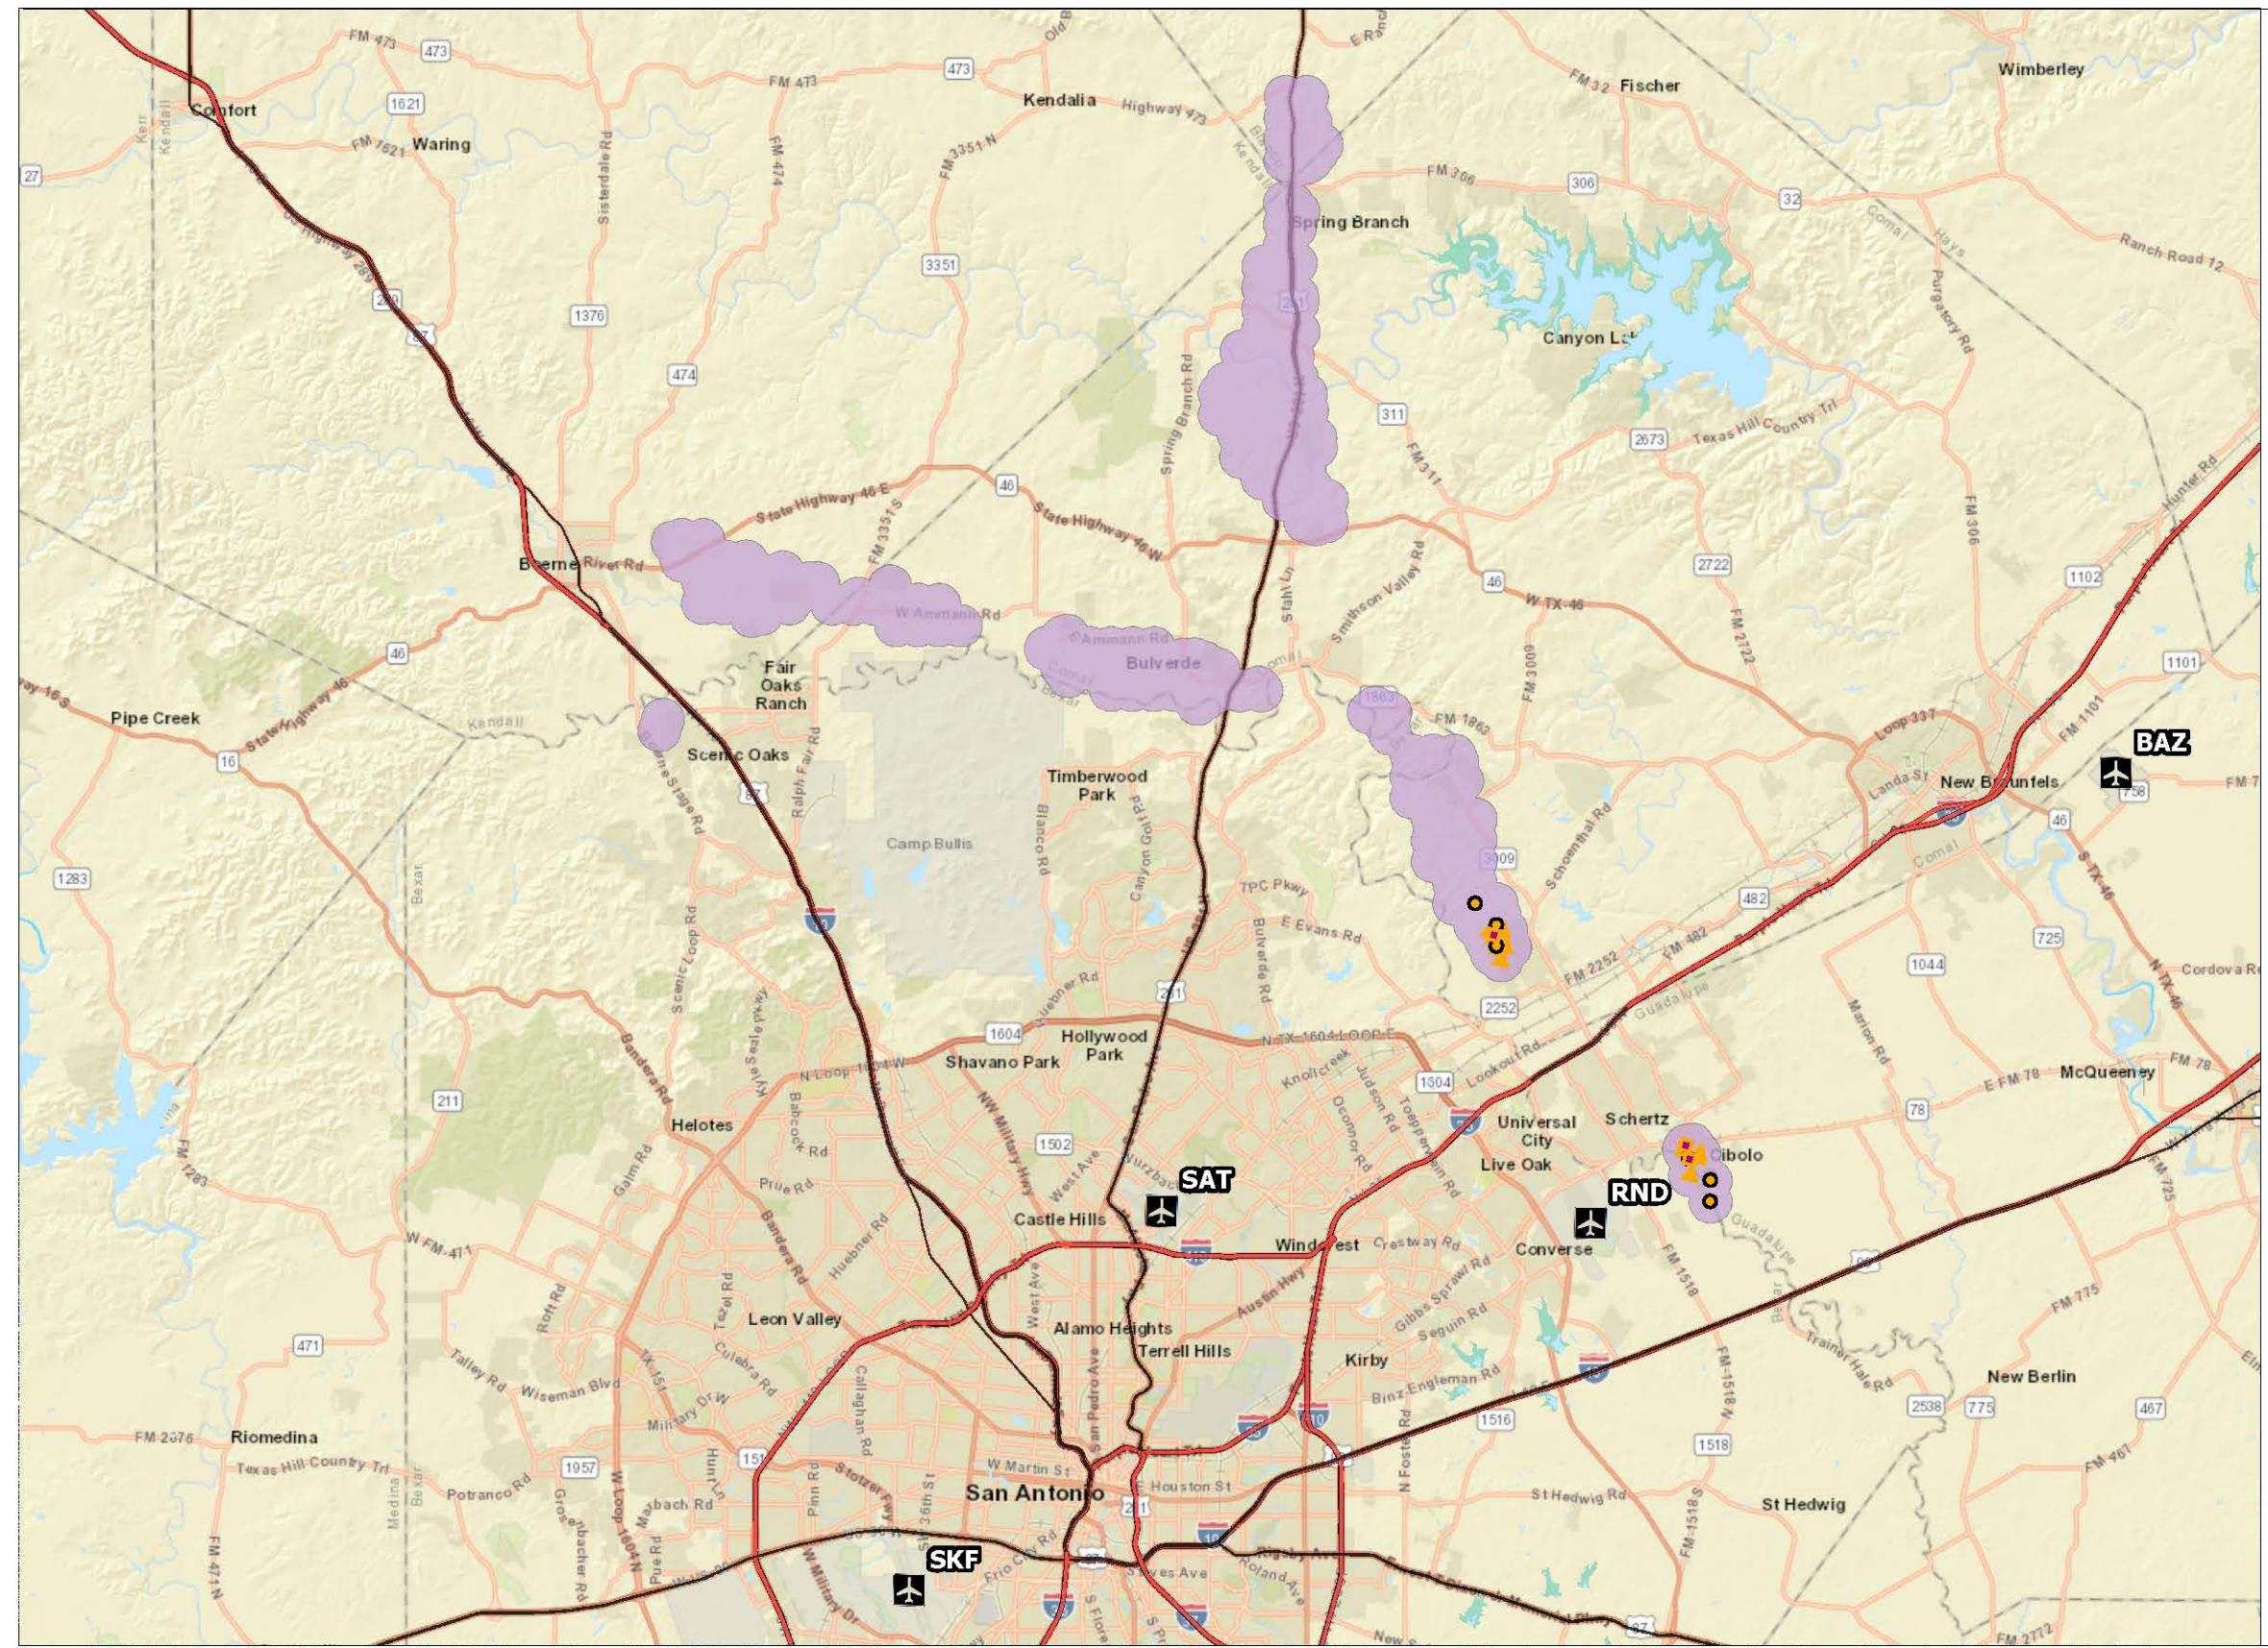

Similar to the population centroid results, the likely cause of the reportable noise increase in the 2023 Proposed Action scenario is attributable to the use of the YODUH SID from RND departures. For the reportable noise increase in the 2028 Proposed Action scenario, the likely causes are the YODUH and ALISS SIDs from departures from RND and the POPPO STAR from SKF arrivals.

#### **5.4.4 Noise Sensitive Land Use Areas**

For all 2023 and 2028 scenarios, the analysis indicates that the Proposed Action would not result in any significant increase in noise in any of the identified Noise Sensitive Land Use Areas. Noise results for these points are provided in **Supplement 6**.

#### **5.4.5 SNIDR Supplemental Study Area**

For all 2023 and 2028 scenarios, the analysis indicates that the Proposed Action would not result in any significant increase in noise in any of the points that intersect the SNIDR Supplemental Study Area. Noise results for these points are provided in **Supplement 7**.

Subject: AEDT Aircraft Substitution Request, Rev. C  
Reference: San Antonio Airspace Modernization Project  
Contract No.: 693KA9-21-D-00007  
Delivery Order: 693KA9-21-F-00005 (DO5)

Dear Kristi:

As part of the San Antonio Airspace Modernization Draft Environmental Assessment (Draft EA), ATAC is developing the inputs for the Aviation Environmental Design Tool (AEDT). AEDT will be used to model the noise effects resulting from proposed changes to the airspace. Consistent with Federal Aviation Administration (FAA) policies and procedures, we submit this request for approval of the San Antonio Airspace Modernization Draft EA identified aircraft types of interest (Attachment A).

While AEDT 3d includes supporting noise data from the legacy environmental tools such as the Integrated Noise Model (INM) version 7.0b and the Noise Integrated Routing System (NIRS) version 7.0b3, as well as its own improvements and additions, certain aircraft types that occur in the regional airspace existing and forecast fleets are not included in the AEDT database. Since this is an airspace study, procedure step profiles for both arrivals and departures are required in order to use altitude controls in AEDT. These altitude controls are important to adequately model the noise impact of different altitude profiles such as existing step-down procedures in comparison to proposed new OPDs. We have attempted to identify surrogate departure and/or arrival aircraft types that would be compatible with AEDT. We request that the FAA review and approve these AEDT 3d substitutes for each of these aircraft types or provide a suitable substitution.

In accordance with FAA policy, we expect that this request will be reviewed by the FAA's Office of Environment and Energy Noise Division (AEE-100). We will be happy to respond to questions regarding this request from yourself or those offices.

Thank you for your assistance on this matter.

Sincerely,

Bill Keller  
ATAC Corporation

Attachments:  
Attachment A: AEDT Aircraft Substitution Requests and Suggestions

## Attachment A: AEDT Aircraft Substitution Requests and Suggestions

The following aircraft types included in the San Antonio Airspace Modernization require an FAA-approved substitution. In each case, a recommended substitute with a similar aircraft type from the existing AEDT 3d database is presented.

FAA AEE provided a SQL query to run against the AEDT databases, which resulted in a table containing AEDT-recommended substitutions. FAA AEE also indicated that if a substitution was covered by the AEDT-recommended substitutions table, a request and subsequent approval is not required.

The methodology used to evaluate aircraft substitutions consisted of first developing a list of aircraft types that require substitutions. The resulting list was cross-referenced against AEDT-recommended substitutions, and if available, the AEDT recommendation would be used. Next, for the aircraft types that were left without an AEDT recommendation, an analysis to determine the best AEDT aircraft substitution was conducted.

**Table 1** presents the San Antonio Airspace Modernization aircraft substitution requests previously submitted by ATAC that have historically been FAA AEE approved. The approvals used for this aircraft substitution request include the Denver Metroplex aircraft substitution approval dated December 3, 2018. The copies of previous aircraft substitution requests and approvals are available upon request. For each row in **Table 1**, the aircraft substitution choices are discussed in subsections following **Table 1**.

**Table 1: Previously Approved Metroplex EA Aircraft Substitutions for San Antonio Airspace Modernization**

### B753

The 757300 (a direct match) was used for the AEDT departure model substitution for the B753. Because there is no arrival procedure step in AEDT for the B753, the substitution 757RR was used for arrivals. This aircraft is a variant of the Boeing 757, and is similar in size, configuration, and engine type.

### B772

The AEDT type 777200 was recommended by the AEDT model substitution database and was used as a departure substitution aircraft for the B772, but the 777200 does not have arrival procedure step profiles available. Thus, for arrivals the AEDT type 7773ER was used. Both of these aircraft are variants of the B772 and are similar aircraft in size, configuration, and engine type.

### B77L

The AEDT type 777300 was recommended by the AEDT model substitution database and was used as a departure substitution aircraft for the B77L, but the 777300 does not have arrival procedure step profiles available. Thus, for arrivals the AEDT type 7773ER was used. Both of these aircraft are variants of the B77L and are similar aircraft in size, configuration, and engine type.

### EXP

The AEDT type GASEPV (General Aviation Single Engine Prop Variable) was used as a substitution aircraft for departures and arrivals for the EXP. The EXP can represent any experimental (piston homebuilt) aircraft. These aircraft can be a general aviation variable pitch propeller aircraft, and therefore GASEPV is a good substitution.

### EXPR

The AEDT type GASEPV (General Aviation Single Engine Prop Variable) was used as a substitution aircraft for departures and arrivals for the Express 2000, EXPR. The EXPR aircraft is a general aviation constant speed propeller aircraft, and therefore GASEPV is a good substitution.

### GL5T

The Bombardier Global Express, with a maximum takeoff weight (MTOW) of 92,500 lb, having 2 x BR710A2-20 engines, each generating 14,750 lb (65.6kN) thrust was mapped to the Gulfstream V (GV), with a MTOW of 90,500 lb (41,050 kg), having 2 × Rolls-Royce BR710A1-10 turbofan engines, each generating 14,750 lb (65.6 kN) thrust each engine. The GL5T aircraft is a variant of the GV and is similar aircraft in size, configuration, and engine type.

### GLEX

The Bombardier Global 6000, with a MTOW of 99,500 lb, having 2 x BR10A2-20 engines, each generating 14,750 lb (65.6 kN) of thrust was mapped to the Gulfstream V (GV), with a MTOW of 90,500 lb (41,050 kg), having 2 × Rolls-Royce BR710A1-10 turbofan engines, each generating 14,750 lb (65.6 kN) thrust each engine. The GLEX aircraft is a variant of the GV and is similar aircraft in size, configuration, and engine type.

### LNC4

The AEDT type GASEPV was used as a substitution aircraft for departures and arrivals for the Columbia Lancair LNC4. The LNC4 aircraft is a general aviation variable pitch propeller aircraft, and therefore GASEPV is a good substitution.

## Attachment A

---

### MD82

The AEDT type MD82 (a direct match) was recommended by the AEDT model substitution database and was used as a departure substitution aircraft for the MD82; however, the MD82 does not have arrival procedure step profiles available within AEDT. Thus, for arrivals the AEDT type MD9025 was used. The MD9025 substitution is the closest available match within AEDT to the MD82 in terms of aircraft size, configuration, and engine type.

### MD83

The AEDT type MD83 (a direct match) was recommended by the AEDT model substitution database and was used as a departure substitution aircraft for the MD83, but the MD83 does not have arrival procedure step profiles available. Thus, for arrivals the AEDT type MD9025 was used. The MD9025 substitution is the closest match within AEDT to the MD83 in terms of aircraft size, configuration, and engine type.

### P51

The AEDT type GASEPV was used as a substitution aircraft for departures and arrivals for the P-54 Mustang. The P51 aircraft is a general aviation variable pitch propeller aircraft, and therefore GASEPV is a good substitution.

### PA20

The PA20 Piper Pacer is a high wing aircraft with O-320 engine. ATAC requests mapping this aircraft to the Cessna 172 Skyhawk airframe, CNA172 ANP\_ID, C172 BADA, and O-320 engine.

### PA44

The AEDT type PA30 was used as a substitution aircraft for the PA44 for both arrivals and departures. Both aircraft are light twin aircraft, and are similar in size and configuration.

**Table 2** presents substitutions for aircraft types that have no historical Metroplex EA precedence. For each row, the aircraft substitution choices are discussed in following subsections.

**Table 2: Aircraft Substitutions for San Antonio Airspace Modernization**

| Aircraft Code | Represented Aircraft      | Operation Type          | AEDT EQUIP_ID | AEDT ANP_ID | AEDT Airframe               | AEDT ENGINE | AEDT BADA |
|---------------|---------------------------|-------------------------|---------------|-------------|-----------------------------|-------------|-----------|
| AC95          | 690/695 Jetprop Commander | Arrivals and Departures | 1541          | DHC6        | Rockwell Twin Commander 690 | 1726        | PAY3      |
| B3XM          | Boeing 737 MAX 10         | Arrivals and Departures | 6383          | 7378MAX     | Boeing 737-9                | 2175        | B39M      |
| FA50          | Dassault Falcon 50        | Arrivals and Departures | 1172          | LEAR35      | Lockheed L-1329 Jetstar II  | 1205        | FA50      |

## **Attachment A**

---

### **AC95**

AC95 is the aircraft designator for a 690/695 Jetprop Commander aircraft, which is a twin-engine light business aircraft. ATAC requests that this be mapped to the Rockwell Twin Commander 690 airframe, DHC6 ANP\_ID, PAY3 BADA, and TPE331-10 engines.

### **B3XM**

B3XM is the aircraft designator for a Boeing 737 MAX 10 aircraft, which is a twin-engine narrow-body airliner. ATAC requests that this be mapped to the Boeing 737-9 airframe, 7378MAX ANP\_ID, B39M BADA, and CFM LEAP-1B27 engines.

### **FA50**

FA50 is the aircraft designator for the Dassault Falcon 50. The Falcon 50 is a French super-midsize, long-range business jet. ATAC requests this aircraft be mapped to the Lockheed L-1329 Jetstar II airframe, LEAR35 ANP\_ID, FA50 BADA, and Allied Signal TFE731-3 engine.

Dear Kristi,

The Office of Environment and Energy (AEE) has received the memo from ATAC dated July 18th, 2022, referencing the San Antonio Airspace Modernization Draft Environmental Assessment (EA). The memo requests approval for non-standard AEDT 3d aircraft substitutions for aircraft types not present in the AEDT database. Additionally, the memo requests approval for non-standard AEDT 3d aircraft substitutions for aircraft that lack procedural step profiles in the AEDT database which are needed to utilize altitude control codes to model altitude profiles for arrivals and departures including existing step-down and proposed new Optimized Profile Descent (OPD) procedures.

AEE has reviewed the proposed substitutions and is providing a list of approvals or required updates in the tables below.

**Table 1: Aircraft not present in the AEDT 3d Database**

- AEE does not approve the proposed substitutions for the Experimental (EXP), Express 2000, Piper PA20, and Piper PA44 aircraft types. Alternative substitutions are provided.
- AEE approves the proposed substitutions for the Lancair LNC4, North American P51, Rockwell 690/695, and Boeing B3XM aircraft types.

**Table 2: Aircraft lacking procedural profiles in the AEDT 3d database**

- AEE does not approve the proposed departure and arrival substitution for the Dassault FA50 aircraft type. An alternative substitution is provided.
- AEE approves the proposed arrival only substitutions for the Boeing B753, Boeing B772, Boeing 77L, McDonnell Douglas MD82, and McDonnell Douglas MD83 aircraft types.
- AEE approves the proposed departure and arrival substitutions for the Bombardier GLEX and GL5T aircraft types.

Table 1: Aircraft Not Present in the AEDT 3d Database

\*Approval of an alternative Dassault Falcon 50 aircraft substitution (AEDT EQUIP\_ID 1318) for arrival operations is provided due to errors in the standard FAL900EX ANP arrival procedural profile when modeled in conjunction with altitude control codes.

Please understand that this approval is limited to this particular Environmental Assessment for the San Antonio Airspace Modernization project and for use with AEDT 3d only. Further non-standard AEDT inputs for additional projects at this or any other site will require separate approval.

Sincerely,

Donald Scata  
Manager  
AEE-100/Noise Division

# 1 Introduction

## 1.1 Background

This submittal contains data and information describing the use and implementation of user-defined procedure profiles in the Federal Aviation Administration's (FAA's) Aviation Environmental Design Tool (AEDT). AEDT is a comprehensive software tool that provides aircraft noise, fuel burn, and emissions information to FAA and its stakeholders. AEDT facilitates environmental review activities required under the National Environmental Policy Act (NEPA) by consolidating the modeling of these environmental impacts in a single tool.

## 1.2 Purpose

Use of non-default methods or data for environmental analysis of FAA actions generally requires written approval from the FAA's Office of Environment and Energy (AEE). AEDT provides pre-packaged default profiles that are appropriate for most studies. In certain situations, user-defined profiles are created. The purpose of this submittal is to obtain permission from AEE to use a user-defined approach profile for the MD11GE arrivals in the San Antonio Airspace Modernization Project.

This submittal follows the guidance put forth in the FAA document titled, "Guidance on Using the Aviation Environmental Design Tool (AEDT) to Conduct Environmental Modeling for FAA Actions Subject to NEPA"<sup>1</sup>. Section 5.3.2, "User-defined Profiles", from the FAA document outlines additional information to include in the submittal package when requesting the use of user-defined profiles. The reason for this request is to acquire permission to utilize user-defined approach procedure steps rather than the default profile points for MD11GE arrivals that is currently implemented in AEDT 3d. Procedure steps instruct how to flight profiles are modeled within AEDT. Because procedure steps are a set of instructions, the modeled flight profile can vary depending on a given trajectory. In contrast, profile points are a set of pre-determined, static points that make up a flight profile. For airspace noise analyses, procedure step profiles are preferred due to their dynamic nature and utilization of altitude control code functionality – modeling aircraft trajectory and performance to a higher fidelity compared to profile point profiles. It is proposed that using user-defined procedure steps is preferable over the use of an aircraft substitution for the MD11GE. This submittal does not include information for the following items that are found in Section 5.3.2 because they are not applicable under the conditions of this request:

- #1 Analysis Demonstrating Change: While the noise receptors spaced at 0.5 nautical miles under the flight path are evaluated, the receptors for Noise Sensitive Areas are not. The Day/Night Noise Level (DNL) exposure levels where the requested profile segment will most likely be applied are primarily levels below DNL 65.
- #2 Concurrence of Aircraft Performance: The request is not related to developing a custom performance climb or descent profile for specific aircraft types.
- #3 Performance Characteristics: The request is not related to developing a custom performance climb or descent profile for specific aircraft types.

---

<sup>1</sup> Federal Aviation Administration. *Guidance on Using the Aviation Environmental Design Tool (AEDT) to Conduct Environmental Modeling for FAA Actions Subject to NEPA*, Retrieved from [https://aedt.faa.gov/2d\\_information.aspx](https://aedt.faa.gov/2d_information.aspx) on May 30, 2018.

## 1.3 Problem Statement

In AEDT 3d, the MD11GE only has profile points available for approaches. Due to the high amount of varying flight trajectories in airspace noise studies, it is not desirable to represent all MD11GE arrival flight trajectories using a single, static fixed-point profile.

Although the DC1030 presents a viable substitution, its noise levels at altitude appear to be less than the MD11GE.

## 1.4 Proposed Solution

The proposed solution is to copy the approach procedure steps from a DC1030 and apply it for the MD11GE approach profile, thus creating a non-standard aircraft model. The non-standard aircraft model would use the approach procedure steps of the DC1030, while maintaining the use of the Noise-Power-Distance (NPD) curve and other attributes (equipment, engine type, etc.) of the MD11GE. NPD data in AEDT is a set of noise levels expressed as a function of engine power (usually the corrected net thrust per engine), and distance.

## 1.5 Statement of Benefit

Implementing the proposed solution in Section 1.4 allows for the retention of the MD11GE noise characteristics while leveraging the similar DC1030 approach profile, which also allows the ability to vary altitude trajectories within the San Antonio Airspace Modernization Project.

# 2 Methodology

This section presents the methodology used to compare the default MD11GE profile points against the MD11GE user-defined procedure step profile. Section 2.1 presents the AEDT modeling methodology, and Section 2.2 presents how performance results were compared.

## 2.1 Modeling Methodology

The resulting altitude, speed, and thrust profiles were compared for a sample MD11GE arrival flight using profile points (default) and user-defined procedure steps described in Section 1.4. Sound Exposure Level (SEL) noise values every half nautical mile along the flight trajectory were also compared between the two versions of the MD11GE.

A straight vector track trajectory landing at San Antonio International Airport (SAT) on Runway 31L was used for the comparison. The operation count was set to '1' for both flights. All annualization factors were set to a value of '1'.

AEDT's option to utilize terrain data when calculating noise values was enabled using data from the United States Geological Survey (USGS). Data from the USGS's digital elevation model in 1 arc second resolution was downloaded, input, and used during runtime affecting the noise values for both the user-defined and default profiles.

The same weather settings in AEDT 3d was used for both flights. The flights were modeled with relevant weather data for the San Antonio Airspace Modernization Project (see Section 3).

## 2.2 Methodology for Analysis of Aircraft Performance Comparison

The objective of this analysis is to demonstrate the magnitude of differences between default and user-defined profiles with respect to aircraft performance. A commonly used measure of the differences between values is the root-mean-square error (RMSE). RMSE is computed by calculating the square root of the average of squared errors. In this application, the error is the

difference between the default value and the user-defined value for each of the three aircraft performance parameters (altitude, speed, and thrust). These differences were calculated every 1 Nautical Mile (NM) along the track until the end of the shorter track is reached, which is approximately 20 NM (see Section 5). RMSE is defined by the following formula where  $\hat{y}$  is equal to user-defined value and  $y$  is the default value.

$$RMSE = \sqrt{\frac{\sum(\hat{y} - y)^2}{n}}$$

A RMSE value of 0 indicates that the default and user-defined values are identical. In general, lower RMSE values indicate the default and user-defined values are similar and higher RMSE values indicate less similarity. It should be noted that comparisons across data types are invalid because RMSE is dependent on the scale of numbers used. In other words, the RMSE for altitude cannot be compared to the RMSE for speed.

### 3 San Antonio Airspace Modernization Project

**Table 3-1** summarizes the amount of MD11GE arrival operations in the San Antonio Airspace Modernization Project for all five scenarios.

**Table 3-1 MD11GE Scaled Arrival Operations per Scenario**

### 3.1 Implementation of Proposed Solution

A new user-defined approach profile for the MD11GE ACFT\_ID named 'STD\_DC10' was created using the same values as the MD11GE STANDARD approach profile found within the FLT\_ANP\_AIRPLANE\_PROFILES table. Thus, retaining the aircraft weight of the MD11GE. The next step was to copy the necessary FLAP\_IDS of the DC1030 from the FLT\_ANP\_AIRPLANE\_FLAPS table and associate them with the MD11GE.

**Table 3-3** presents the default set of flaps available for the DC1030. **Table 3-4** presents the default set of flaps available for the MD11GE as well as the additional flap records that were copied from the DC1030 (shaded in grey for clarity).

**Table 3-3 AEDT Default Flaps for DC1030**

| ACFT_ID | FLAP_ID | OP_TYPE | COEFF_R | COEFF_C_D | COEFF_B  |
|---------|---------|---------|---------|-----------|----------|
| DC1030  | U-20    | A       | 0.104   | 0         | 0        |

 Prepared by: ATAC, July 2022

After all profile inputs for the user-defined aircraft has been added to the AEDT study, all arrival MD11GE AIR\_OPERATIONS were assigned to use the user-defined profile.

## 4 Analysis Demonstrating Change

As outlined in Section 5.3.2 of the “Guidance on Using the Aviation Environmental Design Tool (AEDT) to Conduct Environmental Modeling for FAA Actions Subject to NEPA” document, noise results for arrival tracks should be reported by placing noise receptors 0.5 NM apart underneath the flight path. This analysis and all remaining analysis sections was performed on a straight vector track arriving to SAT on runway 31L.

**Table 4-1** compares the noise output of the modeled track using the MD11GE profile points (default) against the procedure steps user-defined profile. The AEDT aircraft model (also known as “ANP\_ACFT\_ID”) is presented along with the profile weight which describes the starting weight of the aircraft in pounds (lbs). The first column presents the distance from the arriving runway end to the particular noise receptor placed underneath the given track in nautical miles. The second column is the noise value generated from the default profile at each receptor in SEL in decibels (dB). The third column is the noise value generated from the user-defined profile at each receptor in SEL dB. The fourth column is a difference between the third and fourth columns presented in dB. (Due to rounding, this column may contain values that are not accurately represented by the hundredth decimal place.) To capture the noise impacts of the entire approach procedure profile, noise receptors were placed underneath the track until 20 NM of cumulative distance was reached, which is approximately the length of both profiles.

**Table 4-1 Comparative Noise Analysis**

| AEDT Aircraft Model:<br>MD11GE |                                     | Profile Weight:<br>390,000 lbs      |              |
|--------------------------------|-------------------------------------|-------------------------------------|--------------|
| Receptors<br>(NM)              | AEDT Default<br>Profile<br>(SEL dB) | User-Defined<br>Profile<br>(SEL dB) | Diff<br>(dB) |
| 0.5                            | 96.07                               | 98.41                               | 2.34         |

**Table 4-1** shows that noise values generated from the user-defined procedure profile are slightly different from the noise values generated from the default procedure profile, which is the expected result due to the different profiles.

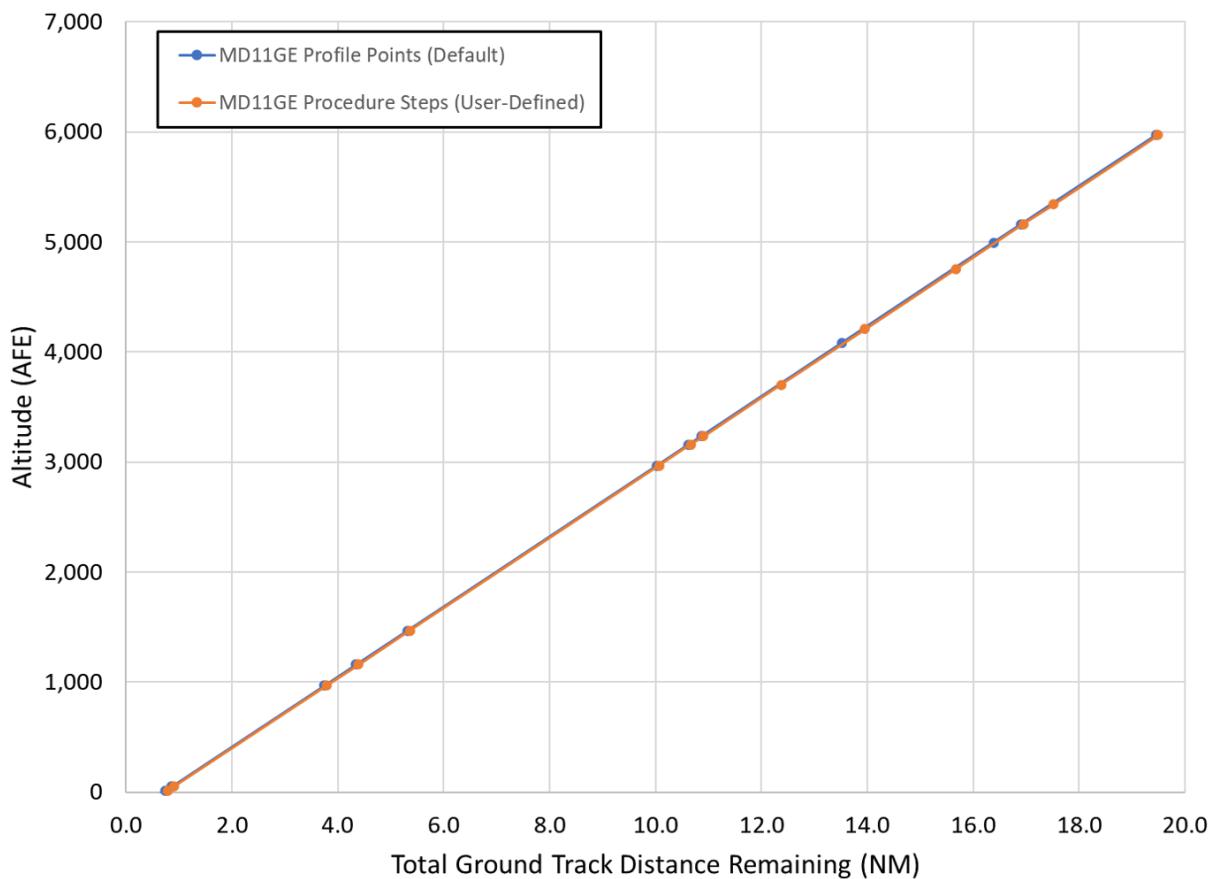

## 5 Graphical and Tabular Comparison

Section 5.3.2 of the “Guidance on Using the Aviation Environmental Design Tool (AEDT) to Conduct Environmental Modeling for FAA Actions Subject to NEPA” document also describes that graphics depicting each proposed change in profile be provided to display the effect on aircraft performance in the three following ways:

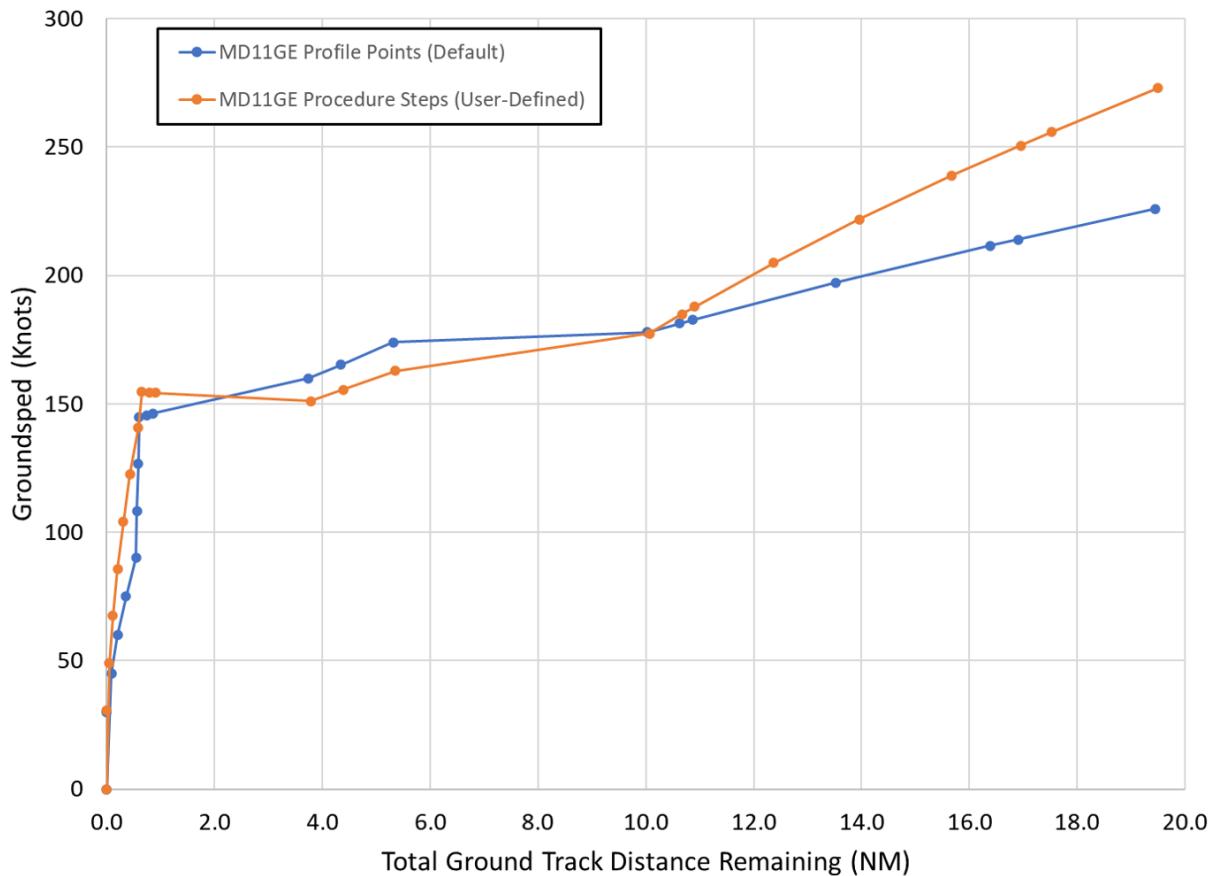

- Altitude vs. Total Ground Track Distance Remaining
- Speed vs. Total Ground Track Distance Remaining
- Thrust vs. Total Ground Track Distance Remaining

This section provides charts for the modeled track plotting total ground track distance remaining until the end of roll in nautical miles along the x-axis versus altitude in feet referenced using Above Airfield Elevation (AFE), speed measured as ground speed in knots, and thrust measured as net corrected thrust in pounds, respectively.

For all charts, the default approach procedure profile will be presented as a blue line and the user-defined approach procedure profile will be presented as a solid orange line. Similar to the comparative noise analysis presented in Section 4, all of the charts presented will be truncated at approximately 20 NM in order to depict the complete approach procedure profile.

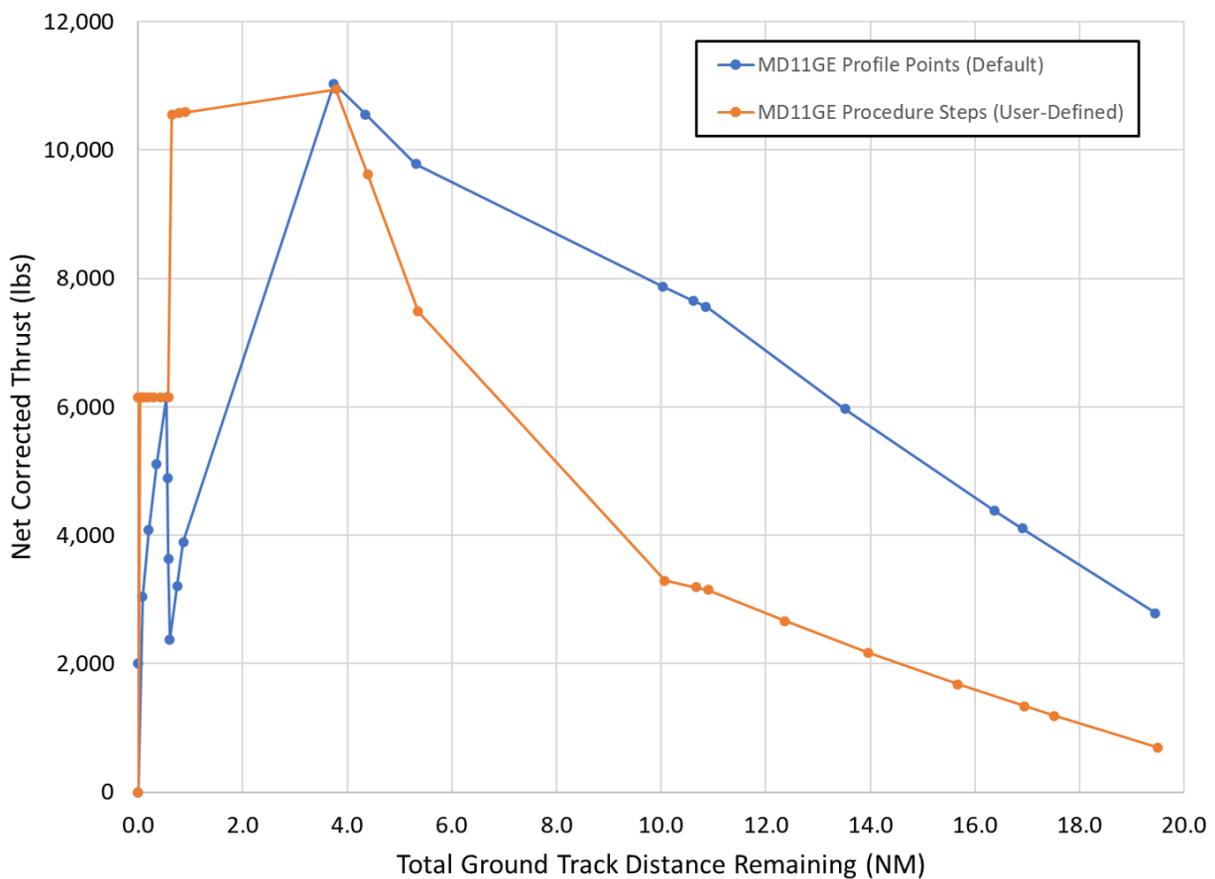

**Exhibit 2 Altitude vs. Total Ground Track Distance Remaining**

Source: ATAC, July 2022  
Prepared by: ATAC, July 2022

**Exhibit 3 Speed vs. Total Ground Track Distance Remaining**

Prepared by: ATAC, July 2022

#### Exhibit 4 Thrust vs. Total Ground Track Distance Remaining

Source: ATAC, July 2022  
 Prepared by: ATAC, July 2022

It can be observed from **Exhibit 2** and **Exhibit 3** that altitude and speed values for the default and user-defined procedure profiles are very similar. **Exhibit 4** shows that net corrected thrust between profiles is different due to the difference in profiles used.

**Table 5-1** contains the data used to plot the graphs found in **Exhibit 2**, **Exhibit 3**, and **Exhibit 4**.

**Table 5-1 Comparative Aircraft Performance**

| MD11GE Profile Points (Default) |                    |               |                             | MD11GE Procedure Steps (User-Defined) |                    |               |                             |
|---------------------------------|--------------------|---------------|-----------------------------|---------------------------------------|--------------------|---------------|-----------------------------|
| Cumulative Distance (NM)        | Altitude (ft. AFE) | Speed (knots) | Net Corrected Thrust (lbs.) | Cumulative Distance (NM)              | Altitude (ft. AFE) | Speed (knots) | Net Corrected Thrust (lbs.) |

## 6 Quantitative Comparison of Results

This section quantitatively compares the results of the default and user-defined profiles for altitude, speed, and net corrected thrust using the methodology presented in Section 2.2. **Table 6-1** presents the RMSE values calculated for each aircraft performance parameter.

**Table 6-1 RMSE Summary Table**

| Parameter | RMSE    |
|-----------|---------|
| Altitude  | 0.009   |
| Speed     | 20.896  |
| Thrust    | 3,390.7 |

Source: ATAC, July 2022  
 Prepared by: ATAC, July 2022

The RMSE values in **Table 6-1** indicate that the aircraft performance of the default and user-defined profiles are similar.

## 7 Conclusion

ATAC is seeking approval for the use of the user-defined approach profile described in Section 1.4 in order to more accurately model MD11GE arrivals. MD11GE arrivals constitutes about 0.6% of the total operations in the San Antonio Airspace Modernization Project. Comparisons show slight differences in altitude vs. distance and slightly larger differences in speed vs. distance between the default and proposed user-defined profile. These factors help explain differences in net corrected thrust, but the noise results do not significantly differ with a maximum difference of 2.34 dB. Small noise differences between the default and proposed user-defined profiles exist; however, the benefit to the model of allowing for dynamic approach profiles using procedure step profiles and altitude control codes exceeds this cost.

Dear Kristi,

The Office of Environment and Energy (AEE) has received the memo from ATAC dated July 18th, 2022, referencing the San Antonio Airspace Modernization Draft Environmental Assessment (EA). The memo requests approval for the use of the DC1030 ANP type arrival procedure profile for use with the MD11GE ANP type, in lieu of its standard fixed point profile data in AEDT 3d. This request was made so that altitude control code functionality not available for aircraft with fixed point profiles, may be used during the modeling process for the MD11GE.

AEE approves the use of an MD11GE non-standard arrival profile based on the DC1030 arrival profile for this purpose.

Please understand that this approval is limited to this particular Environmental Assessment for the San Antonio Airspace Modernization project and for use with AEDT 3d only. Further non-standard AEDT inputs for additional projects at this or any other site will require separate approval.

Sincerely,

Donald Scata  
Manager  
AEE-100/Noise Division

## Supplement 3 – Census Block Noise Results

### S3.1 Reportable Noise Increases 2023

**Table S3.1** identifies the U.S. Census blocks that would experience a DNL 5 dB or greater increase in areas exposed to DNL between 45 dB and 60 dB under the 2023 Proposed Action scenario when compared to the 2023 No Action scenario. **Exhibit 9** in the Noise Technical Report identifies the location of the population centroids for the census block. For the affected centroids, **Table S3.1** provides the U.S. Census block identification number, geographical coordinates (latitude and longitude), population count, the calculated DNL under No Action and Proposed Action conditions for 2023, and the change in DNL. As shown in the table, a total of 573 people, associated with 11 population centroids, would be affected. The population centroids are located in two general areas. The first area is located approximately 12.5 NM east of SAT near the border of Guadalupe and Bexar Counties. The second area is located approximately 10 NM northeast of SAT in Comal County.

**Table S3.1 Reportable Noise Increases in the DNL 45 dB to 60 dB Range 2023**

| Census Block ID | Latitude | Longitude | Population | No Action DNL | Proposed Action DNL | Change |

### S3.2 Reportable Noise Increases 2028

**Table S3.2** identifies the U.S. Census blocks that would experience a DNL 3 dB or greater increase in areas exposed to DNL between 60 dB and 65 dB under the 2028 Proposed Action scenario when compared to the 2028 No Action scenario. **Exhibit 10** in the Noise Technical Report identifies the location of the population centroids for the census block. For the affected centroids, **Table S3.2** provides the U.S. Census block identification number, geographical coordinates (latitude and longitude), population count, the calculated DNL under No Action and Proposed Action conditions for 2028, and the change in DNL. As shown in the table, a total of 100 people, associated with three population centroids, would be affected. The population centroids are located approximately 12.5 NM east of SAT near the border of Guadalupe and Bexar Counties.

**Table S3.2 Reportable Noise Increases in the DNL 60 dB to 65 dB Range 2028**

| Census Block ID | Latitude  | Longitude  | Population | No Action DNL | Proposed Action DNL | Change |
|-----------------|-----------|------------|------------|---------------|---------------------|--------|
| 481872107172025 | 29.556265 | -98.229484 | 35         | 57.0129       | 60.04               | 3.02   |

Prepared By: ATAC Corporation, August 2022.

**Table S3.3** identifies the U.S. Census blocks that would experience a DNL 5 dB or greater increase in areas exposed to DNL between 45 dB and 60 dB under the 2028 Proposed Action scenario when compared to the 2028 No Action scenario. **Exhibit 10** in the Noise Technical Report identifies the location of the population centroids for the census block. For the affected centroids, **Table S3.3** provides the U.S. Census block identification number, geographical coordinates (latitude and longitude), population count, the calculated DNL under No Action and Proposed Action conditions for 2028, and the change in DNL. As shown in the table, a total of 8,068 people, associated with 108 population centroids, would be affected. The population centroids are located in 5 general areas. The first area is located approximately 10 NM northeast of SAT near the border of Bexar and Comal Counties. The second area is located approximately 20 NM north of SAT in Comal and Blanco Counties. The third and fourth areas are located approximately 12 NM north and 17 NM northwest of SAT, respectively. Finally, the fifth area is about 17 NM northwest of SAT in Bexar County.

## Supplement 4 – Section 4(f), Historic, and Cultural Resources Noise Results

### S4.1 Inventory

This supplement provides an inventory of Department of Transportation Act (DOT Act), Section 4(f) (49 U.S.C. § 303; 23 U.S.C. § 138) resources, including historical/cultural properties also covered under Section 106 of the National Historic Preservation Act (NHPA) (16 U.S.C. § 470), that were identified and evaluated as part of the Draft EA.

The inventory of Section 4(f) resources and historical/cultural properties is intended to include all public parks, recreation areas, wildlife and waterfowl refuges, and historic sites, including properties listed on the National Register of Historic Places (National Register) located within the 18,000 Foot Supplemental Study Area and the SNIDR Screening Area. Properties listed on the National Register and considered under both Section 4(f) and Section 106 of the NHPA are included in this supplement. Spatial data for the National Register properties was downloaded from the National Park Service Integrated Resource Management Applications Portal. Spatial data for cultural and park properties was downloaded from readily available federal, state, and local sources. Source information is identified in **Table S4.1**.

## S4.2 Section 4(f), Historic, and Cultural Resources Noise Increases 2023

**Table S4.2** identifies the Section 4(f) resources and historical/cultural properties identified within the General Study Area that would experience a DNL 5 dB or greater increase in areas exposed to DNL between 45 dB and 60 dB under the 2023 Proposed Action scenario when compared to the 2023 No Action scenario. **Exhibit 9** in the Noise Technical Report identifies the location of the points. **Table S4.2** provides a Location Identifier, geographical coordinates (latitude and longitude), place name/description, the calculated DNL under No Action and Proposed Action conditions for 2023, and the change in DNL. Note that some places are in identical geographic coordinates either due to their proximity to each other or having originated from different data resources (see **Table S4.1**), however all named places with unique resource numbering are listed in this table for completeness.

**Table S4.2 Section 4(f), Historic, and Cultural Resources Noise Increases in the DNL 45 dB to 60 dB Range 2023**

| <u>Location ID</u> | <u>Latitude</u> | <u>Longitude</u> | <u>Name</u>               | <u>No Action DNL</u> | <u>Proposed Action DNL</u> | <u>Change</u> |

## S4.2 Section 4(f), Historic, and Cultural Resources Noise Increases 2028

**Table S4.3** identifies the Section 4(f) resources and historical/cultural properties identified within the General Study Area that would experience a DNL 5 dB or greater increase in areas exposed to DNL between 45 dB and 60 dB under the 2028 Proposed Action scenario when compared to the 2028 No Action scenario. **Exhibit 10** in the Noise Technical Report identifies the location of the points. **Table S4.3** provides a Location Identifier, geographical coordinates (latitude and longitude), place name/description, the calculated DNL under No Action and Proposed Action conditions for 2028, and the change in DNL. Note that some of the places are in identical geographic coordinates either due to their proximity to each other or having different labels from different data resources (see **Table S4.1**). All places are listed in this table for completeness.

## S4.3 Section 4(f), Historic, and Cultural Resources Noise Exposure

**Table S4.4** identifies noise values modeled at all of the Section 4(f) resources and historical/cultural properties identified within the 18K Supplemental Study Boundary Area and SNIDR Supplemental Study Area. The inventory includes the Location Identifier, geographical coordinates (latitude and longitude), type, agency, source identifier, name, source, state, and the calculated noise exposure values under 2021/2022 Existing Conditions (EC) and Proposed Action (PA) and No Action (NA) Conditions for 2023 and 2028.

**Table S4.4 Department of Transportation Act, Section 4(f) Properties and Historic and Cultural Resources Inventory and Noise Exposure Results**

For Table S4.4, please see Addendum 2.

## Supplement 5 – One-Half Nautical Mile Grid Noise Results

**Table S5.1** identifies the 0.5 NM Grid points that would experience a DNL 5 dB or greater increase in areas exposed to DNL between 45 dB and 60 dB under the 2023 Proposed Action scenario when compared to the 2023 No Action scenario. **Exhibit 9** in the Noise Technical Report identifies the location of these points. For the affected points, **Table S5.1** provides the location identifier, geographical coordinates (latitude and longitude), the calculated DNL under No Action and Proposed Action conditions for 2023, and the change in DNL.

Prepared By: ATAC Corporation, August 2022.

**Table S5.4** presents the 0.5 NM Grid location identifier, geographical coordinates (latitude and longitude), the calculated DNL under No Action and Proposed Action conditions, as well as the change in DNL for both 2023 and 2028 scenarios, for all 0.5 NM Grid points evaluated in this San Antonio Airspace Modernization Project.

**Table S5.4 0.5 NM Grid Noise Exposure Results**

---

*For Table S5.4, please see Addendum 3*

## **Supplement 6 – Noise Sensitive Land Use Areas Noise Results**

**Table S6.1** identifies noise values modeled at 198 individual grid points representing Noise Sensitive Land Use Areas. The table includes the name, address, type of place, geographical coordinates (latitude and longitude) of the Noise Sensitive Land Use Area and presents the calculated noise exposure values under 2021/2022 Existing Conditions (EC) and Proposed Action (PA) and No Action (NA) Conditions for 2023 and 2028.

**Table S6.1 Noise Sensitive Land Use Area Location and Noise Exposure Results**

## **Supplement 7 – SNIDR Supplemental Study Area Noise Results**

**Table S7.1** identifies noise values modeled at 2007 individual points that intersect the SNIDR Supplemental Study Area (see **Section 2.2.3**). The table includes the Location ID, geographical coordinates (latitude and longitude), and presents the calculated noise exposure values under 2021/2022 Existing Conditions (EC) and Proposed Action (PA) and No Action (NA) Conditions for 2023 and 2028.

**Table S7.1 SNIDR Supplemental Study Area and Noise Exposure Results**
