Finding of No Significant Impact/Record of Decision, and Final Programmatic Environmental Assessment for

FAA-Recognized Identification Areas (FRIAs) under the Remote Identification of Unmanned Aircraft Final Rule (14 CFR Part 89)

June 2023

United States Department of Transportation
Federal Aviation Administration

Washington, D.C.
Notice of Availability of the Final Programmatic Environmental Assessment and Finding of No Significant Impact/Record of Decision for FAA-Recognized Identification Areas (FRIAs)

The Federal Aviation Administration (FAA) hereby gives Notice of Availability (NOA) for the Final Programmatic Environmental Assessment (PEA) and Finding of No Significant Impact/Record of Decision (FONSI/ROD) following the FAA’s evaluation of the potential environmental impacts associated with the approval of FRIA locations, pursuant to the National Environmental Policy Act. FRIAs may be established in accordance with Title 14 Code of Federal Regulation (CFR) part 89. A FRIA is a defined geographic area where unmanned aircraft can be flown without remote identification equipment. Both the unmanned aircraft and the pilot must be located within the FRIA’s boundaries throughout the operation. In addition, the pilot of the unmanned aircraft must be able to see it at all times throughout the duration of the flight. Only FAA-recognized Community Based Organizations and educational institutions such as primary and secondary schools, trade schools, colleges, and universities are eligible to request the establishment of a FRIA. If the FAA approves the establishment of a FRIA, the approval will be valid for 48 calendar months.

The environmental impacts that may result from the FAA’s approval of these limited, location-specific areas for the operation of unmanned aircraft have been considered in a manner consistent with the provisions of the National Environmental Policy Act (NEPA), as amended (42 U.S.C. 4321-4347), the regulations of the Council on Environmental Quality (40 CFR parts 1500-1508), and FAA Order 1050.1F, Environmental Impacts: Policies and Procedures. Based on the analysis described in this PEA, the FAA has determined there will not be a significant impact to the human environment. As a result, an Environmental Impact Statement (EIS) has not been initiated (40 CFR 1501.6).

The Final PEA reflects consideration of comments received during the public comment period for this PEA, which was open from April 3, 2023, until May 3, 2023.

The Final PEA and FONSI/ROD are available to view/download electronically at https://www.faa.gov/uas/advanced_operations/nepa_and_drones/

For any questions or to request a copy of the PEA, please e-mail 9-FAA-Drone-Environmental@faa.gov.

Posted: June 29, 2023

Responsible FAA Official:

Dave Menzimer
Manager, General Aviation Operations Section
General Aviation and Commercial Division
Office of Safety Standards, Flight Standards Service
Introduction

The Federal Aviation Administration (FAA) prepared the attached Final Programmatic Environmental Assessment (PEA) that analyzes and discloses the potential environmental impacts associated with the approval of FAA-Recognized Identification Areas (FRIAs), pursuant to the National Environmental Policy Act (NEPA). FRIAs are locations where people can operate unmanned aircraft (UA) without remote identification.¹ FRIAs may be established in accordance with Title 14 Code of Federal Regulation (CFR) Part 89, herein referred to as the Remote ID Rule. The attached PEA addresses the overall environmental effects of UA operating in FRIAs.

The Final PEA was prepared in accordance with the Council on Environmental Quality (CEQ) regulations and CEQ’s December 18, 2014 guidance on the effective use of programmatic NEPA reviews to evaluate the environmental impacts resulting from the agency approving applications of eligible entities to establish FRIAs. The FAA has developed this program-level review using a consistent framework and methodology, which supports the analyses, documentation, and decisions of subsequent project-level actions. It covers actions that will be taken nationwide and is broad in scope.

Only FAA-recognized Community Based Organizations (CBOs) such as the Academy of Model Aeronautics (AMA), and educational institutions such as primary and secondary schools, trade schools, colleges, and universities are eligible to request the establishment of a FRIA. The FAA has established a process under which it will receive for consideration and action applications from eligible entities to

---

¹ The Remote ID Rule became effective on April 21, 2021, except that Subpart C covering the process for community-based organizations to submit applications to establish FRIA locations became effective on September 16, 2022. In addition, UA manufacturers must comply with the relevant Remote ID requirements by September 16, 2022, and all UA pilots must meet the operating requirements of Part 89 by September 16, 2023. This means that, by September 16, 2023, UA operators must fly either a standard remote identification UA or a UA equipped with a broadcast module, or must limit their operation of a non-compliant UA to an established FRIA location.
establish a FRIA. The FAA has discretion to approve or deny an application to establish a FRIA as set forth in subpart C of the Remote ID Rule. These approvals are a major federal action under NEPA (40 CFR 1508.1(q)). The PEA describes this major federal action and the potential environmental impacts resulting from it.

After completing the PEA, reviewing and analyzing available data and information on existing conditions and potential impacts, and reviewing public comments, the FAA has determined that the proposed action will not significantly affect the quality of the human environment. Therefore, the preparation of an Environmental Impact Statement is not required, and the FAA is issuing this Finding of No Significant Impact (FONSI) and Record of Decision (ROD). The FAA intends for the PEA to create efficiencies by establishing a framework that can be used for “tiering,” where appropriate, to project-specific actions that require additional analysis. As decisions on specific applications are made, to the extent additional NEPA analysis is required, environmental review will be conducted to supplement the analysis set forth in the attached PEA. The FAA has made this determination in accordance with applicable environmental laws and regulations. The PEA is incorporated by reference into and supports this FONSI/ROD.

**Proposed Action**

The proposed action under consideration in the PEA is the determination whether to approve applications to establish FRIAs, which are locations identified by the applicant where the FAA would permit UA operations without remote identification, provided that the UA is within an operator’s visual line of sight and both the UA and the operator remain within the boundaries of the approved area. In addition, operators of UA with remote identification may also operate at FRIA locations pursuant to regulations generally applicable to UA operators. Many of the FRIA establishments will be sought for Academy of Model Aeronautics (AMA) flying clubs and other CBOs.

The FAA has a regulatory duty to consider all applications for a FRIA. After taking into consideration the criteria set forth in 14 CFR 89.215, and reviewing the proposed FRIA location, the FAA will approve or deny an application. The approval of a FRIA application relates to its location and would allow remote pilots to operate UA not equipped with remote identification only within the FRIA boundaries. UA without remote identification would be prohibited in airspace beyond the boundary of an established FRIA. The approval of a FRIA does not include land disturbance, construction, or any other infrastructure development that a private entity may carry out.

See Section 3.1 of the PEA for further information.
Purpose and Need

As required by FAA Order 1050.1F, an environmental assessment must include a discussion of the underlying purpose and need for the proposed action. This includes a discussion of what the FAA plans to achieve by implementing the proposed action (purpose), and the problem that the proposed action is intended to resolve (need).

The purpose of the proposed action is to provide for locations where UA may operate without remote identification. Beginning on the Remote ID Rule operational compliance date (September 16, 2023), FRIAs will be the primary location where UA 0.55 pounds and over may operate without remote identification unless otherwise authorized by the Administrator (14 CFR 89.115(b)). While the FAA anticipates that most operators will comply with the Remote ID Rule through use of either a standard remote identification UA or a UA equipped with a remote identification broadcast module, some operators -- such as those operating amateur or home-built UA lacking remote identification – will only be able to conduct UA operations within the boundaries of a FRIA.

The need for the proposed action is to ensure the safety and security of the National Airspace System (NAS) by ensuring that UA are able to operate safely alongside other users of the NAS, and to provide regulatory relief to those who are not able to come into compliance with the Remote ID Rule by operating a standard remote identification UA or a UA equipped with a remote identification broadcast module.

See Section 2.0 of the PEA for further information.

Alternatives

Alternatives analyzed in detail in the PEA include the proposed action and the no action alternative. Under the no action alternative, the proposed action would not be implemented (the FAA would not approve a FRIA application and consequently a FRIA would not be established). If a proposed FRIA location is not approved, operators of UA with remote identification would still be permitted to operate those UA under 0.55 pounds maximum gross operating weight pursuant to 49 U.S.C. 44809 without obtaining FAA certification or operating authority. However, operators of UA without remote identification would need to shift their operations to an approved FRIA location or cease operations altogether. This alternative does not support the stated purpose and need.

See Section 3.2 of the PEA for further information.
Environmental Impacts

The potential environmental impacts from the proposed action and no action alternative were evaluated in the PEA for each of the environmental impact categories identified in FAA Order 1050.1.F. In the PEA, Section 4 describes the physical, natural, and human environment within the project study area, and identifies those environmental impact categories that are not analyzed in detail, explaining why the proposed action would have no potential effects on those environmental impact categories. Those categories are: Biological Resources (Fish and Plants); Coastal Resources; Farmlands; Hazardous Materials, Solid Waste, and Pollution Prevention; Historical, Architectural, Archaeological, and Cultural Resources; Land Use; Natural Resources and Energy Supply; Socioeconomic Impacts and Children’s Environmental Health and Safety Risks; and Water Resources (Wetlands, Floodplains, Groundwater, and Wild and Scenic Rivers).

Section 4 also provides detailed evaluations of the potential environmental consequences for each of the remaining environmental impact categories and documents the finding that no significant environmental impacts would result from the proposed action. A summary of the documented findings for each category, including requisite findings with respect to relevant special purpose laws, regulations, and executive orders, is presented below:

- **Air Quality, PEA Section 4.3.** Under the Clean Air Act, the EPA has established National Ambient Air Quality Standards (NAAQS) for pollutants of concern known as “criteria pollutants” (40 CFR Part 50). The criteria pollutants are carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO2), ozone (O3), particulate matter less than or equal to 10 microns aerodynamic diameter (PM10), fine particulate matter less than or equal to 2.5 microns aerodynamic diameter (PM2.5), and sulfur dioxide (SO2). The NAAQS represent the maximum levels of air pollution that are considered acceptable, with an adequate margin of safety, to protect public health (Primary Standards) and welfare (Secondary Standards). Short-term standards (1-, 3-, 8-, and 24-hour averaging periods) are established for pollutants contributing to acute health effects, while long-term standards (quarterly and annual averages) are established for pollutants contributing to chronic health effects.

In addition to the ambient air quality standards for criteria pollutants, regulations exist for hazardous air pollutants (HAPs) emitted from stationary sources. The National Emission Standards for Hazardous Air Pollutants, established by EPA under the Clean Air Act, regulate 188
The EPA General Conformity Rule (40 CFR 93 Subpart B) ensures that the actions taken by federal agencies in nonattainment and maintenance areas conform to a state’s plan to meet the NAAQS. The General Conformity Rule applies to federal actions occurring in nonattainment or maintenance areas. It provides that a federal agency cannot issue a permit for or support an activity unless the agency determines that the action will conform to the most recent EPA-approved State Implementation Plan. This means that projects using federal funds or requiring federal approval must not: cause or contribute to any new violation of a NAAQS; increase the frequency or severity of any existing violation; or delay the timely attainment of any standard, interim emission reduction, or other milestone.

The affected environment at flying locations seeking a FRIA approval typically will include landscaped grassy areas, paved areas, gravel, forest edges, recreational parks, airports, and agricultural areas, typically in suburban or rural settings. Existing air emissions may come from fuel-powered UA operating at the flying location, as well as surrounding manmade sources. While many FRIA locations would be located in non-attainment or maintenance areas, the FAA anticipates that a majority of FRIA locations would not be located in nonattainment or maintenance areas based on the geographic dispersal of UA flying locations around the U.S. Because of the wide dispersal of established and future flying locations that may be affected by FRIA approvals, and the complexity of resources potentially affected, it is not possible to provide a detailed comprehensive description of locally affected environments in the PEA.

Under the proposed action, the FAA anticipates that there would be no change in baseline conditions due to the generally enabled activities permitted by 49 U.S.C. 44809 and 14 CFR parts 107. As described in the Air Emissions Technical Report (Appendix A), air emissions from UA operations at FRIA locations would not cause significant impacts to air quality because it is not possible for UA operations to contribute to an exceedance of any regulatory standard. At both existing and new locations seeking a FRIA approval, there will be minimal or no change in air emissions as a result of the no action alternative; therefore, no new impacts will occur.

- **Biological Resources (Wildlife), PEA Section 4.4.** Biological resources include plant and animal species and their habitats, including special status species (federally listed or state-listed...
threatened or endangered species, species proposed for listing, species that are candidates for federal listing, marine mammals, and migratory birds) and environmentally sensitive or critical habitat.

The Endangered Species Act (ESA) of 1973 requires the evaluation of all federal actions to determine whether a proposed action is likely to jeopardize any proposed, threatened, or endangered species or proposed or designated critical habitat. Federal agencies are responsible for determining if an action “may affect” listed species or critical habitat, which determines whether formal or informal consultation with the U.S. Fish and Wildlife Service (USFWS) and/or the National Marine Fisheries Service (NMFS) is needed. If the FAA determines that the action will have no effect on listed species, consultation is not required. If the FAA determines that the action may affect listed species, consultation with the USFWS must be initiated.

The Migratory Bird Treaty Act of 1918 protects migratory birds, including their nests, eggs, and parts, from possession, sale, purchase, barter, transport, import, export, and take. The USFWS is the federal agency responsible for the management of migratory birds as they spend time in habitats of the U.S. The Bald and Golden Eagle Protection Act of 1940 prohibits anyone from “taking” a bald or golden eagle, including their parts, nests, or eggs, without a permit issued by the USFWS. The USFWS National Bald Eagle Management Guidelines, provide for additional protections against “disturbances.” Similar to take, “disturb” means to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, injury to an eagle or causes either a decrease in its productivity or nest abandonment due to a substantial interference with breeding, feeding, or sheltering.

Special status species are those species for which state or federal agencies provide an additional level of protection by law, regulation, or policy. Included in this category are federally listed species that are protected under the ESA, species considered as candidates for such listing, bald and golden eagles (protected by the Bald and Golden Eagle Protection Act), and those species that are state-listed as threatened, endangered, or of special concern, or otherwise protected by federal or state laws. Special status species are broadly distributed throughout the United States. Special status avian species (birds, bats, flying insects) would likely be at greatest risk from UA operations. Examples of federally listed threatened and endangered avian species include the Red-cockaded Woodpecker, Piping Plover, Bachman’s Warbler, Gray Bat, and Miami
Blue Butterfly. As shown in Table 1-1 of the PEA, the current USFWS list of threatened and endangered species includes 1,481 animal species and 939 plant species in the United States.

ESA candidate species are plants and animals for which the USFWS has sufficient information on their biological status and threats to propose them as endangered or threatened under the ESA, but for which development of a proposed listing regulation is precluded by other higher priority listing activities.

The Migratory Bird Treaty Act (MBTA) protects 1,093 migratory birds across the United States from capture, pursuit, hunting, or removal from natural habitat. Migratory bird species include those that nest in the United States and Canada during the summer and then migrate to and from the tropical regions of Mexico, Central and South America, and the Caribbean for the non-breeding season. A variety of birds protected under the MBTA could occur in or around flying locations where UA are flown.

The USFWS also identifies birds of conservation concern (BCC), which are migratory and non-migratory bird species not already listed under the ESA that represent the highest avian conservation priorities. The BCC list is based on an assessment of several factors, including population abundance trends, threats on breeding and nonbreeding grounds and size of breeding and nonbreeding ranges. A total of 134 individual bird species in the Continental United States were listed in the BCC 2021 report. Examples of BCC include the Mountain Plover, Red Knot, Reddish Egret, Eastern Whip-poor Will, and Snowy Owl.

At both existing and new FRIA locations, impacts to threatened and endangered species and critical habitat would be expected to stay the same once a FRIA is approved, as there would be no real change in the environmental baseline. Therefore, the FAA has determined that FRIA approvals would have no effect on threatened and endangered species.

During the FRIA application approval process, if the FAA determines that the establishment of a FRIA is likely to jeopardize the continued existence of proposed threatened and endangered species or result in destruction of or adverse modification of proposed critical habitats, the FAA would coordinate with the appropriate USFWS office, and a tiered environmental assessment

---

(EA) could be required if effects to threatened and endangered species may occur, or if the destruction of or adverse modification of habitat cannot be avoided. Resource avoidance for specific FRIA approvals may occur for resources such as critical habitat for threatened or endangered species, special habitat management units, sensitive species areas, and important breeding, roosting or foraging areas. Buffer distances are typically established through consultation with the regulatory agency to avoid an ‘incidental take’ by disturbance or harassment of protected species, such as those protected under the ESA and the Bald and Golden Eagle Protection Act.

Federally listed endangered and threatened species, state-listed species, and migratory birds may occur at FRIA sites. However, since the baseline affected environment includes existing UA operations, there will be little, if any, change to analyze for the affected environment. Additionally, there will be no changes to terrestrial or aquatic environments. UA operations at these flying locations will be within a small, limited operating area and are not expected to impact critical lifecycles of wildlife species or their ability to survive.

Under the no action alternative, no new impacts will occur to vegetation/flora, wildlife/fauna and rare, threatened, and/or endangered species. The no action alternative will not result in any construction-related habitat disturbances. The no action alternative assumes that a FRIA would not be approved, but that UA operators may still fly at the proposed location using Remote ID broadcast technology. Consequently, there will be no new impacts to biological resources as a result of the no action alternative.

- **Climate, PEA Section 4.5.** FAA Order 1050.1F requires consideration of potential climate impacts. The FAA has not established a significance threshold for climate effects, and has not identified any factors to consider in making a significance determination for greenhouse gas (GHG) emissions. The FAA does not expect the direct or indirect effects from the proposed action to contribute to the temperature and weather effects of global climate change as compared to the overall effect of the aviation sector on global climate change.

The Air Quality Assessment for FRIAs (Appendix A of PEA) shows that the emissions would be extremely small in the context of regional, national, and global emissions. The proposed action alternative would not result in substantive changes to activity levels and their associated GHG
emissions at new and existing flying locations. Therefore, GHG emissions from UA operations at new and existing FRIA locations would not cause significant impacts to climate.

The no action alternative would not result in substantive changes to activity levels and their associated GHG emissions at new and existing flying locations. If a FRIA application is rejected, no new substantial GHG emissions are expected to occur. Consequently, there will be no new impacts to climate as a result of the no action alternative.

- **Department of Transportation (DOT) Act, Section 4(f) Resources, PEA Section 4.6.** Section 4(f) of the DOT Act protects significant publicly owned parks, recreational areas, wildlife and waterfowl refuges, and public and private historic sites. Section 4(f) provides that the Secretary of Transportation may approve a transportation program or project requiring the use of publicly owned land of a public park, recreation area, or wildlife or waterfowl refuge of national, state, or local significance, or land of an historic site of national, state, or local significance, only if there is no feasible and prudent alternative to using that land and the program or project includes all possible planning to minimize harm resulting from the use.

Section 4(f) properties include parks and recreational areas of national, state, or local significance that are both publicly owned and open to the public; publicly owned wildlife refuges of national, state, or local significance that are open to the public; and historic sites of national, state, or local significance in public or private ownership regardless of whether they are open to the public. Due to the nationwide scope of the proposed action, Section 4(f) properties likely are located in the study area.

The FAA has determined that some existing flying locations have been established in state and local public parks, although it is assumed that these operators have approval from the park authority in order to conduct their activities within the park. UA flying activities in public parks would generally be located away from other activities or protected areas within the park.

The FAA has not found any existing flying locations at historic sites or wildlife refuges, and this would not be expected to change in the future since the relevant authorities overseeing historic sites and wildlife refuges are not likely to approve a UA flying location at these types of properties.
Impacts on Section 4(f) properties would be significant if the proposed action involves more than a minimal physical use of a Section 4(f) resource or constitutes a constructive use based on an FAA determination that the project would substantially impair the Section 4(f) resource.

The FAA has determined that infrequent UA overflights as described in the proposed action will not cause substantial impairment to Section 4(f) resources that could occur in the study area and would not be considered a constructive use of any Section 4(f) resource. There will be no physical use of Section 4(f) resources. Noise and visual effects from occasional UA overflights are not expected to diminish the activities, features or attributes of the resources that contribute to their significance or enjoyment. Additionally, based on the FAA’s analysis, there will be no change in the environmental baseline as a result of FRIA approvals. Therefore, the proposed action would not result in significant impacts to Section 4(f) resources.

Under the no action alternative, impacts to Section 4(f) resources would be expected to stay the same. As there would be no apparent change in the environmental baseline, there would be no significant impacts as a result of the no action alternative.

- **Noise and Noise-Compatible Land Use, PEA Section 4.7 and Appendix B.** The FAA has issued requirements for assessing aircraft noise in FAA Order 1050.1F, Appendix B. The FAA’s required noise metric for aviation noise analysis is the yearly Day-Night Average Sound Level (DNL) metric. A significant noise impact is defined in Order 1050.1F as an increase in noise of DNL 1.5 dB or more at or above DNL 65 dB noise exposure or a noise exposure at or above DNL 65 dB level due to a DNL 1.5 dB or greater increase.

To ensure that noise would not cause a significant impact to any residential land use or other noise sensitive resources within or adjacent to flying locations seeking a FRIA approval, the FAA initiated an analysis of the potential noise exposure that could result from the proposed action. The noise analysis methodology detailed in Appendix B of the PEA was used to calculate DNL for various operational counts and aircraft types. The results of the analysis show that, for the measured UA, the number of Average Annual Day (AAD) flight events and associated flight times required to produce DNL 65 dB at a fixed receiver location within a flight area is generally much higher than what would be likely or practically possible to occur in foreseeable real-world conditions.
Based on expected UA operations at proposed FRIA flying locations, which typically involves one UA in the air at a time, with operations lasting a few hours per day up to seven days per week, the proposed action’s estimated DNL is less than DNL 65 dB (see the Noise Analysis Report in Appendix B). Additionally, the proposed action would not increase noise exposure levels by DNL 1.5 dB within a DNL 65 dB noise exposure corridor. Therefore, the proposed action would not result in significant noise impacts.

The no action alternative is not expected to result in significant noise impacts given the average sound levels of the UA, the short duration of operations, and the number of daily operations at any given flying location. Consequently, impacts to noise as a result of the no action alternative would not result in significant noise impacts.

- **Visual Effects (Visual Resources and Visual Character), PEA Section 4.8.** Visual resources and visual character impacts deal with the extent to which the proposed action would result in visual impacts to resources in the operating area. Visual impacts can be difficult to define and evaluate because the analysis is generally subjective, but are normally related to the extent that the proposed action would contrast with, or detract from, the visual resources and/or the visual character of the existing environment. In this case, visual effects would be limited to the introduction of a visual intrusion – a UA in flight – which could be out of character with the landscapes where proposed FRIA sites are located.

The proposed action makes no changes to any landforms, or land uses, thus there would be no effect to the visual character of the area. The proposed action would not result in construction or a change in land use and would not affect the visual character of flying locations and adjacent properties. Due to the relatively small size of UA, views from the ground would likely be possible within half a mile, and may be obscured by trees, houses, or other structures due to the low altitudes where the UA operate. Additionally, since UA are already authorized to fly in these locations, there would be no change in the environmental baseline as a result of FRIA approvals. Therefore, no increased impacts to visual resources would result from the proposed action. Any impacts to visual resources under the proposed action would be similar to the no action alternative. Therefore, the proposed action would not result in significant visual effects.

The no action alternative is not expected to result in significant impacts to visual resources or visual character from UA operations and vehicle use or foot traffic. Activities at flying locations
generally take place during daytime hours and would not result in significant light emissions impacts.

**Cumulative Impacts**

As discussed in Chapter 4 of the PEA, it is anticipated that the proposed action will not impact several environmental impact categories (see Section 4.1) and will result in minimal impacts on others. Under the proposed action, UA operations would occur infrequently and typically at locations where flying locations already exist and where those operations are not expected to change as compared to the no action alternative. The proposed action’s potential to contribute to cumulative impacts on any resource is limited to any other operations that might occur at the location at the same time the UA are flying. Given the nature of the proposed action, the locations where UA operations would occur, and the minimal expected impacts of the proposed action, the proposed action would not be anticipated to result in cumulative impacts to environmental resources within the operating area.

**Public Involvement and Coordination**

The Draft PEA was made available for public review. The public Notice of Availability (NOA) was posted on April 3, 2023, to the Federal Register. The Draft PEA was available on the FAA’s website and was open for comment from April 3, 2023, until May 3, 2023. The FAA received three responses during the comment period for this PEA. Appendix D of the attached PEA contains the FAA’s summary and response to timely comments.

**Finding**

The FAA finding is based on a comparative examination of environmental impacts for each of the alternatives studied during the environmental review process. The PEA discloses the potential environmental impacts for each of the alternatives and provides a full and fair discussion of those impacts. Based on the FAA’s review and analysis of the attached Final PEA and consideration of comments, the agency has determined that there would be no significant impacts to the natural environment or surrounding population as a result of the proposed action.

The FAA believes the proposed action best fulfills the purpose and need identified in the PEA. In contrast, the no action alternative fails to meet the purpose and need identified in the PEA. An FAA decision to take the required actions and approvals is consistent with its statutory mission and policies.
supported by the findings and conclusions reflected in the environmental documentation and this FONSI.

Decision and Order

After careful and thorough consideration of the facts contained herein, the undersigned finds that the proposed federal action is consistent with existing national environmental policies and objectives as set forth in Section 101 of NEPA and other applicable environmental requirements and will not significantly affect the quality of the human environment or otherwise include any condition requiring consultation pursuant to Section 102(2)(C) of NEPA. As a result, the FAA will not prepare an Environmental Impact Statement.

Accordingly, under the authority delegated to me by the Administrator of the FAA, I approve and direct that agency action be taken to carry out implementation of the Proposed Action.

Right of Appeal

This FONSI/ROD constitutes a final order of the FAA Administrator and is subject to the exclusive judicial review under 49 U.S.C. § 46110 by the U.S. Circuit Court of Appeals for the District of Columbia or the U.S. Circuit Court of Appeals for the circuit in which the person contesting the decision resides or has its principal place of business. Any party having substantial interest in this order may apply for a review of the decision by filing a petition for review in the appropriate U.S. Court of Appeals no later than 60 days after the order is issued in accordance with the provisions of 49 U.S.C. § 46110.
Final Programmatic Environmental Assessment for

FAA-Recognized Identification Areas (FRIAs) under the Remote Identification of Unmanned Aircraft Final Rule (14 CFR Part 89)

1.0 INTRODUCTION

1.1 Overview

The National Environmental Policy Act of 1969 (NEPA), 42 United States Code (U.S.C.) § 4321 et seq., requires Federal agencies to consider the potential environmental impacts of proposed Federal actions. The Council on Environmental Quality (CEQ) has issued implementing regulations at 40 CFR parts 1500-1508. The Federal Aviation Administration (FAA) has established a process to ensure compliance with the provisions of NEPA through FAA Order 1050.1F, Environmental Impacts: Policies and Procedures (Order 1050.1F).

The CEQ regulations encourage consideration and evaluation of common actions in a programmatic manner to gain efficiencies. The CEQ regulations also encourage program-level environmental analysis when projects are similar to each other and have similar impacts. The FAA is preparing this Programmatic Environmental Assessment (PEA) in accordance with the CEQ regulations and CEQ’s December 18, 2014 guidance on the effective use of programmatic NEPA reviews to evaluate the environmental impacts resulting from the agency approving applications of eligible entities to establish FAA-recognized identification areas (FRIAs). FRIAs are locations where people can operate unmanned aircraft (UA) without remote identification.4

This document will help to ensure consistent and timely environmental evaluations for FRIA applications, and avoid unnecessary duplication and repetition in evaluating the potential environmental impacts of FRIA location approvals. The FAA has developed this program-level review using a consistent framework and methodology, which supports the analyses, documentation, and decisions of subsequent project-level actions. This PEA addresses the overall environmental effects of UA operating in FRIAs. It covers actions that will be taken nationwide and is broad in scope. It may not assess in detail some of the potential significant issues that could be raised at individual FRIA locations. Detailed information about some of the potential FRIA locations is not currently available. While the FAA expects the majority of requests to establish FRIA locations to correlate with existing locations of hobbyist clubs associated with the Academy of Model Aeronautics, and educational institutions such as JROTC schools, not all eligible entities5 are yet known to the FAA. Eligible entities may include organizations who do not currently operate UA at a specific location, but which may be formed in the future and would also be eligible to establish FRIAs. Therefore, this PEA makes assumptions about some unknowns using best available information and, where appropriate, professional expertise.

The FAA will conduct reviews of individual requests to establish FRIAs to ensure that they reflect the environmental impacts and assumptions set forth in this document. As such, some individual FRIA locations may require additional environmental analysis and documentation. However, any subsequent environmental review may be tiered from the PEA, requiring the environmental review to focus only on the specific issue at the FRIA location that falls outside the review of this PEA. The FAA will conduct an

---

4 The Remote ID Rule became effective on April 21, 2021, except that Subpart C covering the process for community-based organizations to submit applications to establish FRIA locations became effective on September 16, 2022. In addition, UA manufacturers must comply with the relevant Remote ID requirements by September 16, 2022, and all UA pilots must meet the operating requirements of Part 89 by September 16, 2023. This means that, by September 16, 2023, UA operators must fly either a standard remote identification UA or a UA equipped with a broadcast module, or must limit their operation of a non-compliant UA to an established FRIA location.

5 Eligible entities include FAA-recognized community-based organizations and educational institutions including primary and secondary educational institutions, Junior Reserve Officers' Training Corps (JROTC) programs, trade schools, colleges, and universities. 14 CFR 89.205.
additional focused environmental analysis in accordance with 40 CFR §§ 1501.11 (tiering), 1501.12 (incorporation by reference), and 1508.1(ff). If the PEA addresses in sufficient detail impacts raised by a particular application then no additional review would be necessary.

Pursuant to 14 CFR Part 89, herein referred to as the Remote ID Rule, the FAA has established a process under which it will receive for consideration and action applications from eligible entities to establish a FRIA. The FAA has discretion to approve or deny an application to establish a FRIA as set forth in subpart C of the Remote ID Rule. These approvals are a major Federal action under NEPA (40 CFR 1508.1(q)). This PEA describes this major Federal action and the potential environmental impacts resulting from it.

1.2 Background

Through the FAA Modernization and Reform Act of 2012, Public Law No. (P.L.) 112-95, § 333 (49 U.S.C. § 44807), Congress tasked the FAA with integrating unmanned aircraft systems (UAS) into the national airspace system (NAS). As a result, the FAA authorized certain UA to operate in the NAS pursuant to 49 U.S.C. § 44809 and 14 CFR Part 107.6 Under these existing operating authorities, UA may be operated throughout the United States provided those operations comply with existing legal requirements. The UA types operated in the NAS include fixed-wing, helicopters, and multicopters, which may be equipped with an electric motor, gas engine, or turbine engine.7

In 2021, the FAA issued the Remote ID Rule, which can best be analogized as digital license plates for UA. The rule imposed remote identification requirements on UA operating in the NAS. These requirements can be met in one of three ways: (1) operating a standard remote identification UA; (2) operating a UA equipped with a remote identification broadcast module; or (3) operating at a FRIA. These compliance mechanisms are set forth in Figure 1, below:

---

6 Part 107 is only applicable to UA that weigh less than 55 pounds at takeoff. To fly a UA that exceeds the maximum weight limit of Part 107 or if the UA mission includes a non-waivable rule, operators may apply for an exemption in accordance with 14 CFR Part 11 and 49 U.S.C. § 44807.

7 The term UA includes conventional model aircraft. Some larger model aircraft (termed “giant scale”) may be operated in FRIAs, but these are far less common than UA weighing less than 55 pounds.
The Remote ID Rule set forth two key deadlines for UA flying in the NAS. First, starting September 16, 2022, the FAA requires that most new UA be manufactured with remote identification. Second, starting September 16, 2023, UA operators will be required to ensure their UA are remote identification compliant or operate at a FRIA; the latter of which is the subject of this PEA. UA with remote identification can continue to operate nationally pursuant to FAA regulation without any change. UA without Remote ID may be operated within FRIA boundaries as long as the UA remain within the operator’s visual line of sight (VLOS) and neither the operator nor the UA travel beyond the FRIA’s boundaries.

Subpart C of the Remote ID Rule established a path through which eligible entities may seek approval from the FAA to establish FRIAs where UA operators who are unable or unwilling to equip their aircraft with remote identification may continue to operate. Subpart C also provides accommodations for FAA-recognized community-based organizations (CBOs) to request locations where individuals, particularly recreational flyers of UA without remote identification may operate. Educational institutions may also request to establish FRIA locations where science, technology, engineering, and math (STEM) curricula and workforce development programs may operate UA not equipped with remote identification. The FAA expects that most UA will comply with remote identification requirements, thereby limiting the

---

8 Figure available: [https://www.faa.gov/uas/getting_started/remote_id](https://www.faa.gov/uas/getting_started/remote_id)
need for FRIAs. However, the FAA estimates that it may receive more than 4,000 FRIA applications by the full Remote ID Rule compliance date of September 16, 2023.

This PEA does not include an analysis of temporary use events such as air shows or drone racing events as the FAA is not planning to approve FRIAs for temporary use events. The FAA’s decision to not include temporary events is because a FRIA, once approved, is valid for four years. As such, the regulatory framework of part 89 precludes the use of a FRIA for temporary events. This PEA analyzes the potential environmental impacts of the FAA approving applications to establish FRIAs, those involving both existing and new flying locations:

- **Existing Locations:** This category comprises: (a) locations with active UA operations currently being used by educational institutions, including Junior Reserve Officer Training Corps (JROTC) programs and post-secondary institutions with UAS-related course offerings, and (b) locations with active UA operations currently used by existing or prospective CBOs, including the Academy of Model Aeronautics (AMA)\(^9\) and non-AMA member organizations.

  UA operators in these areas may operate fixed-wing, helicopter, and multicopter UA equipped with an electric motor, piston engine, or turbine engine. It is expected that AMA locations that are established as a FRIA location would continue to permit these operations. The FAA anticipates that the reasonably foreseeable maximum operational capacity at existing CBO locations will remain the same. Similarly, the FAA anticipates that the VLOS boundaries of these locations, existing UA operations, UA types, and operating characteristics will remain static. Based on information provided by the AMA, the FAA estimates that approximately 2,500 existing locations associated with the AMA may request FRIAs between September 2022 and September 2023. In addition, the FAA estimates that an additional 100 locations at which UA operations currently take place but which are not associated with the AMA may also seek FRIA establishments during the same time period.

  The educational locations are likely to be on landscaped property owned by educational institutions, such as sport fields and stadiums, parking lots, or other open lots. The FAA anticipates that existing average annual operations will remain the same. Similarly, the FAA anticipates that the boundaries of these locations, UA types, and operating characteristics remain static. Based on the Regulatory Impact Analysis prepared by the FAA in conjunction with the Remote ID Rule, it is anticipated that, between September 2022 and September 2023, educational institutions may request to establish FRIAs at approximately 1,800 locations where UA are currently operated.

---
\(^9\) The FAA estimates that AMA flying locations comprise approximately 95 percent of known recreational flying club locations associated with CBOs in the U.S.
1.0 Introduction

Figure 2 Remote Controlled Aircraft Flying Location

Figure 3 Ned Brown Model Airplane Flying Field at Busse Woods, Illinois

10 Figure available: https://www.rc-airplane-world.com/
11 Figure available: https://www.rc-airplane-world.com/
• **New Locations:** This category comprises proposed FRIA locations that are not currently being used by an educational institution or CBO to operate UA, but where UA operators may already be operating in the area in compliance with existing operating authorities. Based on information provided by AMA, the FAA estimates that approximately 80-85 new locations may seek FRIAs annually between September 2022 and September 2027. The FAA also anticipates that non-AMA member organizations recognized by the FAA as a CBO may seek to establish approximately four new FRIAs annually between September 2022 and September 2027. As with existing educational locations, the FAA anticipates that these locations would be established on landscaped school-owned property and likely to be located on open lots. It is also possible that the locations may be established on property otherwise being used for an aviation-related use or where UA currently operate in compliance with legal requirements. The FAA anticipates that educational institutions may establish as many as 625 new FRIAs between September 2022 and September 2027. This assumption is informed by changes in STEM curricula being offered in primary and secondary school.

The Proposed Action in this PEA is the FAA’s determination whether to approve applications for FRIA establishments. The FAA approval of a FRIA only relates to its location and airspace activities in the NAS. It does not approve construction or other infrastructure development. The FAA’s decision regarding a FRIA is dependent on whether: (1) an eligible entity\(^{13}\) submitted the application; and (2) whether the application satisfies the criteria established in 14 CFR § 89.215.\(^{14}\) The analysis of environmental impacts is an important and integral part of the FAA’s decision whether to approve or deny the application.

---

\(^{12}\) Figure available: https://www.ttownmedia.com/tracy_press/our_town/drone-pilot-class-lifts-off/article_88208cc6-129e-11e8-93c7-3747ffe7c8cf.html

\(^{13}\) Eligible entities are defined in 14 CFR 89.205.

\(^{14}\) In considering an application to establish a FRIA, the FAA may consider the four following criteria:
If the FAA approves a request to establish a FRIA, it will be valid for 48 calendar months from the date of approval. To renew the FRIA, the holder must submit a request for renewal no later than 120 days before the expiration date. Any desire to change a FRIA’s geographic boundaries must be sent to the FAA for review.

In this document, the FAA integrated the review process required under other potentially applicable environmental and cultural resource statutes, such as Section 106 of the National Historic Preservation Act (NHPA) and Section 7 of the Endangered Species Act (ESA). This PEA provides the public and the FAA Responsible Official with the information to understand and evaluate the potential environmental consequences of the proposed action and alternative. The FAA Responsible Official will consider the ability of each alternative to meet the purpose and need prior to determining whether to issue a Finding of No Significant Impact (FONSI) or a notice of intent to prepare an Environmental Impact Statement (EIS).

1.3 Public Involvement

The FAA created a Notice of Availability (NOA) with information about the PEA and posted it on the Federal Register. The NOA provided information about the Proposed Action and requested review and comments on this PEA, which was published on the FAA website in April 2023 for a 30-day comment period. Interested parties were invited to submit comments on any environmental concerns related to the Proposed Action by May 3, 2023. The FAA received three responses on the PEA during the public comment period. Appendix D contains the FAA’s responses to timely comments.

(a) The existence of any FAA established flight or airspace restriction limiting the operation of unmanned aircraft systems, such as special use airspace designations under Part 73 of this chapter, temporary flight restrictions issued under Part 91 of this chapter, or any other special flight rule, restriction or regulation in this chapter limiting the operation of unmanned aircraft systems in the interest of safety, efficiency, national security and/or homeland security, which overlaps with the proposed FAA-recognized identification area;

(b) The safe and efficient use of airspace by other aircraft;

(c) The safety and security of persons or property on the ground; and

(d) The need for an FAA-recognized identification area in the proposed location and proximity of other FAA-recognized identification areas.

These criteria are not exhaustive. The FAA may take other considerations into account.

FRIA duration and renewal requirements are found in 14 CFR 89.225

See amendment requirements in 14 CFR 89.220(b)
2.0 PURPOSE AND NEED

The FAA has prepared this PEA to evaluate the potential environmental impacts associated with the determination whether to approve or deny applications to establish FRIAs (the Proposed Action). As required by FAA Order 1050.1F, an environmental assessment must include a discussion of the underlying purpose and need for the Proposed Action. This includes a discussion of the problem that the Proposed Action is intended to resolve (need) and what the FAA plans to achieve by implementing the Proposed Action (purpose).

The purpose of the Proposed Action is to provide for locations where UA may operate without remote identification. Beginning on the Remote ID Rule operational compliance date (September 16, 2023), FRIAs will be the primary location where UA 0.55 pounds and over may operate without remote identification unless otherwise authorized by the Administrator (14 CFR 89.115(b)). While the FAA anticipates that most operators will comply with the Remote ID Rule through use of either a standard remote identification UA or a UA equipped with a remote identification broadcast module, some operators -- such as those operating amateur or home-built UA lacking remote identification – will only be able to conduct UA operations within the boundaries of a FRIA. CBOs may request a FRIA to accommodate recreational flyers who are unable to equip their UA with remote identification. In addition, to encourage participation in aviation for educational purposes, such as STEM programs, the Remote ID Rule provides that educational institutions, including institutions of primary and secondary education, trade schools, JROTCs, colleges, and universities may also apply to establish a FRIA. In addition to recreation and education, FRIAs may be used to support workforce development training.

The need for the Proposed Action is to ensure the safety and security of the NAS by ensuring that UA are able to operate safely alongside other users of the NAS, and to provide regulatory relief to those who are not able to come into compliance with the Remote ID Rule by operating a standard remote identification UA or a UA equipped with a remote identification broadcast module.
3.0 PROPOSED ACTION AND NO ACTION ALTERNATIVE

Two alternatives are evaluated in this PEA: The Proposed Action and the No Action Alternative. No other action alternatives are evaluated because the proposed action is the only available alternative that meets the purpose and need to approve FRIAs in accordance with the Remote ID Rule. Decisions about whether individual applications meet the approved FRIA criteria and program objectives would be made on location-specific proposals as they are submitted to the FAA for action.

3.1 Proposed Action

The Proposed Action under consideration in this PEA is the determination whether to approve applications to establish FRIAs, which are locations identified by the applicant where the FAA would permit UA operations without remote identification, provided that the UA is within an operator’s visual line of sight and both the UA and the operator remain within the boundaries of the approved area. In addition, operators of UA with remote identification may also operate at FRIA locations pursuant to regulations generally applicable to UA operators. Many of the FRIA establishments will be sought for AMA flying clubs and other CBOs.

The FAA has a regulatory duty to consider all applications for a FRIA. After taking into consideration the criteria set forth in 14 CFR 89.215, and reviewing the proposed FRIA location, the FAA will approve or deny an application. The approval of a FRIA application relates to its location and would allow remote pilots to operate UA not equipped with remote identification only within the FRIA boundaries. UA without remote identification would be prohibited in airspace beyond the boundary of an established FRIA. The approval of a FRIA does not extend to land disturbance, construction, or any other infrastructure development that a private entity may carry out.

3.2 No Action Alternative

Under the No Action Alternative, the Proposed Action would not be implemented (the FAA would not approve a FRIA application and consequently a FRIA would not be established). Recreational flyers would still be permitted to operate UA under 0.55 pounds maximum gross operating weight pursuant to 49 U.S.C. 44809 without obtaining FAA certification or operating authority. FAA regulations at 14 CFR Part 107 set forth the requirements for safe and secure flight and enabled remote pilots to decide whether, when, and how often to operate over people, over moving vehicles, or at night. It aligned UA operations to the regulatory scheme of General Aviation (GA) operating under Visual Flight Rules (VFR), found in 14 CFR Part 91. Part 107 permits operators holding a remote pilot certificate with a small UAS rating to conduct UA operations at groundspeeds at or below 100 mph, an altitude below 400 feet above ground level (AGL), and within line of sight of a visual observer(s).

Ownership and operations of UA are distributed throughout the country, with denser ownership and use in more densely populated parts of the country. Following the FAA’s issuance of the Part 107 rule and amendments, the FAA’s 2020 forecasts determined that approximately 1.32 million UA distinctly identified as recreational aircraft were owned at the end of 2019, and estimated that ownership rates would continue to grow annually at approximately 6 percent per annum before plateauing at approximately 1.5 million UA as the pace of falling prices diminishes and early adopters of UA begin to experience limits in their experiments, or as eagerness plateaus. In addition to recreational UA operations, the FAA registration data shows that 385,000 commercial UA were registered by the end of 2019 and such operations are expected to increase under Part 107.
If the FAA does not approve an application to establish a FRIA, most UA operations expected in that area would still be enabled through alternate methods. For example, UA operators have publicly stated that many models and types of UA can comply with the requirements of the Remote ID Rule via a software update or through the installation of an after-market broadcast module. Therefore, the FAA expects that most UA will comply with the Remote ID Rule to operate throughout the NAS in accordance with existing regulations and requirements, and will not need the regulatory relief through FRIs.

Alternatively, if their proposed FRIA location is not approved, operators of UA without remote identification would need to shift their operations to an approved FRIA location or cease operations altogether.
4.0 AFFECTED ENVIRONMENT and ENVIRONMENTAL CONSEQUENCES

This chapter presents nationwide information on existing environmental conditions and evaluates the potential environmental effects of the alternatives being considered. This PEA measures “effect” as a noticeable change caused by FRIA approvals at existing and new UA flying locations. The degree of change is estimated by measuring the difference between the baseline conditions and the effects that result from the designation of the FRIA. As stated in 40 CFR § 1508.1(g), effects include direct, indirect, and cumulative effects. The terms “effect” and “impact” are used interchangeably in this document.

Effects are changes to the human environment from the proposed action or alternatives that are reasonably foreseeable. Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions which may have both beneficial and detrimental effects, even if on balance the agency believes that the effects will be beneficial.

Direct effects are caused by the action and occur at the same time and place. Indirect effects are defined as “effects which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems” (40 CFR § 1508.1(g)(2)).

Once an effect is identified, a determination is made whether an impact is significant. NEPA reviews require consideration of both the potentially affected environment and degree of the impact evaluated (40 CFR § 1501.3). Significance varies with the setting of the proposed action, and should consider the degree of effects across both time (short vs. long-term effects) and space (local vs. regional scale). Under CEQ regulations, the purpose of an EA is to determine whether a proposed action has potentially significant impacts, thus triggering preparation of a detailed EIS.

This chapter also describes conditions and procedures for tiered site-specific environmental review where needed. The FAA will evaluate issues specific to individual FRIA approvals that may have aspects beyond the scope of the environments and potential environmental effects reviewed in this PEA. That evaluation will utilize information from FRIA applicants to complete additional analysis that may include review of resources such as U.S. Fish and Wildlife Service (USFWS) official species lists, noise exposure calculations, and input from relevant agencies and experts.

4.1 Environmental Impact Categories

This section provides a description of the environmental resources that could be affected by the proposed action, as required by the CEQ regulations and FAA Order 1050.1F. The level of detail provided in this section is commensurate with the impact on these resources (40 CFR § 1502.15). The study area for each resource is the entire area within the proposed FRIA location boundaries where FRIA applications are anticipated by the FAA, as discussed in Chapter 3 in this PEA. Not all of these locations are currently known to the FAA. As required by FAA Order 1050.1F, this PEA presents an evaluation of impacts for the environmental impact categories listed below.

- Air Quality
- Biological Resources (Wildlife)
- Climate
4.0 Affected Environment and Environmental Consequences

- Department of Transportation Act, Section 4(f) Resources
- Noise and Compatible Land Use
- Visual Effects (including Light Emissions)

For each of the resources covered in this section, the following information is provided:

- Regulatory Setting
- Affected Environment
- Environmental Consequences

EAs are intended to be concise documents that focus on aspects of the human environment that may be affected by the proposed action. As stated in Chapter 3, the primary difference between what would occur under the proposed action and the no action alternative is that UA operating in a FRIA would be approved to operate without Remote ID broadcasting, while UA outside of a FRIA would be required to broadcast Remote ID information as specified under 14 CFR Part 89. Under the proposed action, the frequency of drone operations and the number of drones used in a proposed FRIA location would not be expected to increase as compared to the no action alternative. Given the nature of the proposed action and the size of the study area, the description of the affected environment is provided at a high level.

4.2 Resources Not Analyzed in Detail

This PEA does not analyze potential impacts on the following environmental impact categories in detail, for the reasons explained below:

- **Biological Resources (Fish and Plants)** – The proposed action does not involve development or disturbance of any land or aquatic habitat. Any overflight of these resources would not affect them. The terrestrial areas where remote pilots will stand while operating UA are already disturbed or landscaped. Any landing and recovery of a UA (either on purpose or accident) beyond the areas where remote pilots will be standing and operating their UA would have little, if any, impact on vegetation due to the relatively small size of the UA and the infrequency with which accidental or emergency landings would occur. Therefore, the proposed action would not affect aquatic and plant resources.

- **Coastal Resources** – The proposed action would not directly affect any shorelines, change the use of shoreline zones, or be inconsistent with any National Oceanic and Atmospheric Administration (NOAA)-approved state Coastal Zone Management Plan (CZMP). The designation of a FRIA is an air safety approval relating to Remote ID broadcasting, and the approval of a FRIA designation does not extend to ground operations that would occur under the proposed action or the no action alternative. Therefore, the proposed action would not affect coastal resources.

- **Farmlands** – The proposed action will not involve the development or disturbance of any land regardless of use, nor would it have the potential to convert any farmland to non-agricultural uses. Therefore, the proposed action would not affect farmlands.

- **Hazardous Materials, Solid Waste, and Pollution Prevention** – The proposed action will not result in any construction or development or any physical disturbances of the ground. Additionally, UA are typically made from recoverable materials that can be properly managed at the end of their operating lives. The FAA has found that proposed FRIA sites are typically not
located at Environmental Protection Agency (EPA) Superfund sites, and even if a FRIA were to be located at a Superfund site, there would be no ground disturbance and therefore no effects to any contaminated sites including Superfund sites. Therefore, the potential for impacts in relation to hazardous materials, solid waste, and pollution prevention is not anticipated.

- **Historical, Architectural, Archaeological, and Cultural Resources** – The proposed action does not involve development or disturbance of any land. The proposed action may result in minor, infrequent, and short-term visual and auditory effects at resources near proposed FRIA locations. However, most FRIA locations already exist as established flying locations and there will be little or no changes in operations as a result of a FRIA approval. The FAA has determined that the proposed action (or undertaking) does not have the potential to cause effects to historic properties, assuming historic properties were located near a proposed FRIA site. As noted above, the proposed action involves temporary, infrequent and short-term drone operations above FRIA locations where UA are currently authorized to operate. Accordingly, the proposed action would not have the potential to cause effects to historic or tribal cultural resources.

- **Land Use** – The proposed action will not involve any changes to existing, planned, or future land uses at proposed FRIA sites. Therefore, the FAA finds that there will be no effects to land use.

- **Natural Resources and Energy Supply** – The proposed action will not require the need for unusual natural resources and materials, or those in short supply. Most UA at a proposed FRIA location will be battery powered, and fuel-powered UA will not consume enough fuel to affect natural resources or energy supply. Therefore, the proposed action would not affect natural resources and energy supply.

- **Socioeconomic Impacts, Environmental Justice, and Children’s Environmental Health and Safety Risks** – The proposed action will not involve acquisition of real estate, relocation of residents or community businesses, disruption of local traffic patterns, loss in community tax base, or changes to the fabric of the community. Therefore, the proposed action would not result in socioeconomic impacts.

The proposed action does not involve the development or disturbance of any land. The proposed action only designates that UA may fly at the location without Remote ID broadcasting. Most of these sites are already operating as UA flying locations and there will be little or no change in operations as a result of a FRIA approval. The proposed action would not result in effects that would be predominately or uniquely borne by a minority or low-income population. Therefore, the proposed action does not have the potential to result in impacts that disproportionately adversely affect a minority or low-income population.

Executive Order (EO) 13045, *Protection of Children from Environmental Health Risks and Safety Risks*, requires federal agencies to ensure that children do not suffer disproportionately from environmental or safety risks. The proposed action will not affect products or substances that a child would be likely to come into contact with, ingest, use, or be exposed to, and would not result in environmental health and safety risks that could disproportionately affect children. Some FRIAs will be designated at educational sites, but the types of activities occurring at a flying location will not cause negative environmental health or safety risks to children whether the location receives a FRIA approval or not.
• **Water Resources (Wetlands, Floodplains, Surface Waters, Groundwater, and Wild and Scenic Rivers)** – The proposed action does not authorize or involve any ground-disturbing activities and would therefore not encroach upon areas designated as navigable waters, wetlands, or floodplains. Any overflight of these resources would not affect them. The proposed action would not result in any changes to existing discharges to water bodies, create a new discharge that would result in impacts to surface waters, or modify a water body. The proposed action would not involve activities that would withdraw groundwater from underground aquifers or reduce infiltration or recharge to ground water resources through the introduction of new impervious surfaces. The proposed action does not have the potential to disrupt the free-flowing character of any designated wild and scenic rivers and Nationwide Rivers Inventory (NRI) segments. Therefore, the proposed action would not affect wetlands, floodplains, surface waters, groundwater, or wild and scenic rivers.

4.3 **Air Quality**

4.3.1 **Regulatory Setting**

*National Ambient Air Quality Standards*

Under the Clean Air Act, the EPA has established National Ambient Air Quality Standards (NAAQS) for pollutants of concern known as “criteria pollutants” (40 CFR Part 50). The criteria pollutants are carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO₂), ozone (O₃), particulate matter less than or equal to 10 microns aerodynamic diameter (PM₁₀), fine particulate matter less than or equal to 2.5 microns aerodynamic diameter (PM₂.₅), and sulfur dioxide (SO₂). The NAAQS represent the maximum levels of air pollution that are considered acceptable, with an adequate margin of safety, to protect public health (Primary Standards) and welfare (Secondary Standards). Short-term standards (1-, 3-, 8-, and 24-hour averaging periods) are established for pollutants contributing to acute health effects, while long-term standards (quarterly and annual averages) are established for pollutants contributing to chronic health effects.

Areas that are and have historically been in compliance with the NAAQS are designated by EPA as attainment areas. Areas that violate a NAAQS are designated as nonattainment areas. Areas that have transitioned from nonattainment to attainment are designated as maintenance areas and are required to adhere to maintenance plans to ensure continued attainment.

*Hazardous Air Pollutants*

In addition to the ambient air quality standards for criteria pollutants, regulations exist for hazardous air pollutants (HAPs) emitted from stationary sources. The National Emission Standards for Hazardous Air Pollutants, established by EPA under the Clean Air Act, regulate 188 HAPs for stationary sources based on available control technologies (40 CFR Parts 61 and 63). The majority of HAPs are volatile organic compounds (VOCs).

HAPs emitted from mobile sources are called Mobile Source Air Toxics (MSATs). MSATs are compounds emitted from highway vehicles and non-road equipment which are known or suspected to cause cancer or other serious health and environmental effects. In 2001, the EPA issued its first MSAT Rule, which identified 21 compounds as being HAPs that required regulation.¹⁷ A subset of six of these MSAT compounds were identified as having the greatest influence on health and included benzene, 1,3-

butadiene, formaldehyde, acrolein, acetaldehyde, and diesel particulate matter. The EPA issued a second MSAT Rule in February 2007, which generally supported the findings in the first rule and provided additional recommendations of compounds having the greatest impact on health. The rule also identified several engine emission certification standards that must be implemented.

**General Conformity**

The EPA General Conformity Rule (40 CFR 93 Subpart B) ensures that the actions taken by federal agencies in nonattainment and maintenance areas conform to a state’s plan to meet the NAAQS. The General Conformity Rule applies to federal actions occurring in nonattainment or maintenance areas. It provides that a federal agency cannot issue a permit for or support an activity unless the agency determines that the action will conform to the most recent EPA-approved State Implementation Plan. This means that projects using federal funds or requiring federal approval must not:

1. Cause or contribute to any new violation of a NAAQS;
2. Increase the frequency or severity of any existing violation; or
3. Delay the timely attainment of any standard, interim emission reduction, or other milestone.

A conformity applicability analysis is the first step of a conformity evaluation and assesses if a federal action must be supported by a conformity determination. This is typically done by quantifying applicable direct and indirect emissions that are proposed to result from a federal action. Direct emissions are those that are caused by or initiated by the federal action and occur at the same time and place as the action. Indirect emissions are those caused by the federal action, but occur later in time and/or removed in distance from the action. The emissions change due to the project (the net emissions) is compared to the *de minimis* threshold specified in the General Conformity Rule for each pollutant. If the results of the applicability analysis indicate that the net emissions would not exceed the *de minimis* emission thresholds applicable to the Proposed Action, then the conformity evaluation process is completed. If emissions of one or more applicable pollutants exceed a *de minimis* threshold, then the project must demonstrate conformity under one of the methods prescribed by the General Conformity Rule.

**4.3.2 Affected Environment**

Because of the wide dispersal of established and future flying locations that may be affected by FRIA approvals, and the complexity of resources potentially affected, it is not possible to provide a detailed comprehensive description of locally affected environments in this PEA. Instead, this chapter characterizes resources in general terms.

As shown in Figures 1 through 6, existing CBO and educational flying locations can be found in all 50 states. These sites have small footprints where the UA must be kept within line of sight. Even in the most densely concentrated regions of flying locations, such as the Northeastern U.S., a person would not be likely to encounter a flying location unless they are actively seeking to do so.

Figure 8 Distribution of JROTC School Locations in the Continental U.S.

Image: Google Earth, as modified by the FAA.
4.0 Affected Environment and Environmental Consequences
The affected environment at flying locations seeking a FRIA approval typically will include landscaped grassy areas, paved areas, gravel, forest edges, recreational parks, airports, and agricultural areas, typically in suburban or rural settings. Existing air emissions may come from fuel-powered UA operating at the flying location, as well as surrounding manmade sources. While many FRIA locations would be located in non-attainment or maintenance areas, the FAA anticipates that a majority of FRIA locations would not be located in nonattainment or maintenance areas based on the geographic dispersal of UA flying locations around the U.S.\(^{25}\)

### 4.3.3 Environmental Consequences

An evaluation of air emissions impacts involves a comparison of current and future proposed air emissions at UA flying locations, and a determination of the extent to which the alternatives may cause an increase in air emissions if a FRIA designation is approved. There is the potential for an air emissions impact to occur when an activity directly or indirectly results in regulated air emissions.

#### Proposed Action Alternative

Under the proposed action, the FAA anticipates that there would be no change in baseline conditions due to the generally enabled activities permitted by 49 U.S.C. 44809 and 14 CFR parts 107. As described in the Air Emissions Technical Report (Appendix A), air emissions from UA operations at FRIA locations would not cause significant impacts to air quality because it is not possible for UA operations to contribute to an exceedance of any regulatory standard.

The air emissions analysis was conducted based on a representative set of recreational UA and applying EPA emissions factors for similar engine types, assuming conservative (e.g. longer duration) flight times for the UA. Annual emissions from each UA were compared to worst case EPA \textit{de minimis} thresholds for each criteria pollutant at both new and existing flying locations. The analysis is based on direct emissions associated with UA operations.

For the analysis, the potential of exceeding the NAAQS was determined by estimating potential UA engine emissions using conservative assumptions and comparing them to worst-case EPA \textit{de minimis} thresholds for significance. The analysis evaluated various commonly-used engine types and estimated the number of hours of operation it would take to exceed the worst-case \textit{de minimis} thresholds. In lieu of specific aircraft model engine emission factors, the EPA Motor Vehicle Emission Simulator (MOVES) non-road model was used to assign similar engine types within its database to the various common UA engine types to generate emissions factors for NAAQS criteria pollutants, assuming gasoline usage for fuel. The hours of operation per year needed for a worst-case hypothetical engine to exceed \textit{de minimis} thresholds was determined. The worst-case \textit{de minimis} thresholds (the lowest \textit{de minimis} thresholds by pollutant based on attainment designation), represent emission quantities of a NAAQS-regulated pollutant, or its applicable precursors, over which the Proposed Action in an EPA designated nonattainment or maintenance area may cause or contribute to a new or continued violation of the NAAQS. Annual emissions below the \textit{de minimis} are considered not significant and are presumed to not exceed the NAAQS.

The results of the analysis show that exceeding the \textit{de minimis} thresholds for nearly all pollutants, assuming worst-case engine ratings and emission factors, would require total annual engine operating hours greater than the 8,760 total hours in a year for all pollutants except the maximum engine horsepower (HP) case for VOCs. Even for the maximum HP engine case for VOCs, the estimated hours to

\(^{25}\) Map of counties designated “nonattainment”. Available: [https://www3.epa.gov/airquality/greenbook/mappoll.html](https://www3.epa.gov/airquality/greenbook/mappoll.html)

exceed the worst-case VOC threshold are 8,208 hours per year, which is highly unlikely to occur in real world circumstances.

For FRIAs approved at an existing flying location, the FAA anticipates that there would be no change in existing conditions due to the generally enabled activities permitted by 14 CFR Part 107 and the location-specific limitations on UA operations and UA operators in Part 89. Furthermore, it is expected that most recreational operators of UA would bring their non-compliant aircraft into compliance either by the Remote ID deadline or sometime after. Potential decreases in flight activity, assuming non-compliant operators cease flying, following the September 2023 compliance deadline would be temporary and negligible. As such, the Proposed Action would not result in substantive changes to activity levels and their associated pollutant emissions at existing flying locations. Emissions from operations at FRIAs established at existing locations would not cause significant impacts to air quality, and it is improbable for UA operations to contribute to an exceedance of any regulatory standard.

For FRIAs designated at newly established flying locations, the FAA anticipates a de minimis change in existing conditions due to the presence of generally enabled activities permitted by 14 CFR Part 107 and the minor changes expected in UA operators’ behavior due to location-specific limitations on UA operations and UA operators in Part 89. A temporary concentration of activity may occur at new locations that previously did not experience multiple operators within a confined area; however, the cumulative nature of these operations would still not trigger anything other than a negligible change to pollutant emissions. As such, the Proposed Action would not result in substantive changes to activity levels and their associated pollutant emissions at new flying locations. Emissions from operations at FRIAs at newly established flying locations would not cause significant impacts to air quality.

Additionally, the FAA anticipates that transportation emissions from UA operators’ traveling to/from FRIA locations would not generate significant impacts because, due to the temporary presence of these vehicles in the area, their emissions would not accrue to levels that would result in significant impacts to air quality and the environment.

In summary, since the emissions individually and collectively are below the worst-case de minimis thresholds, it can be concluded that the operation of UA would “not cause a significant air quality impact, since it is unlikely the pollutant emissions analyzed would exceed a NAAQS.” This conclusion applies to both existing and new flying locations, and at existing and reasonably foreseeable activity levels. Therefore, there would be no significant impact to air quality.

**No Action Alternative**

Under the no action alternative, UA activities at CBO and educational institution flying locations would still occur. If the FAA does not approve an application to establish a FRIA, most UA operations expected in that area would still be enabled. As described in Chapter 3, UA operators would be permitted to operate their aircraft under 14 CFR Part 107 and 49 U.S.C. 44809 at flying locations without obtaining FAA certification or operating authority; the main difference is that the UA would need to comply with Remote ID requirements. At both existing and new locations seeking a FRIA approval, there will be minimal or no change in air emissions as a result of the no action alternative; therefore, no new impacts will occur.
4.4 Biological Resources (Wildlife)

4.4.1 Regulatory Setting

Biological resources include animal species and their habitats, including special status species (federally listed or state-listed threatened or endangered species, species proposed for listing, species that are candidates for federal listing, marine mammals, and migratory birds) and environmentally sensitive or critical habitat. In addition to their intrinsic values, biological resources provide aesthetic, recreational, and economic benefits to society.

Special Status Species

The Endangered Species Act of 1973 [16 U.S.C. § 1531 et seq.] requires the evaluation of all federal actions to determine whether a proposed action is likely to jeopardize any proposed, threatened, or endangered species or proposed or designated critical habitat. Critical habitat includes areas that will contribute to the recovery or survival of a listed species. Federal agencies are responsible for determining if an action “may affect” listed species, which determines whether formal or informal consultation with the USFWS and/or the National Marine Fisheries Service (NMFS) is needed. If the FAA determines that the action will have no effect on listed species, consultation is not required. If the FAA determines that the action may affect listed species, consultation with the USFWS must be initiated.

A significant impact to federally-listed threatened and endangered species would occur when the USFWS or NMFS determines that the proposed action would be likely to jeopardize the continued existence of a federally-listed threatened or endangered species, or would be likely to result in the destruction or adverse modification of federally-designated critical habitat. An action need not involve a threat of extinction to federally listed species to meet the NEPA standard of significance. Lesser impacts including impacts on non-listed or special status species could also constitute a significant impact.

The Migratory Bird Treaty Act (16 U.S.C. §§ 703-712) protects migratory birds, including their nests, eggs, and parts, from possession, sale, purchase, barter, transport, import, export, and take. The USFWS is the federal agency responsible for the management of migratory birds as they spend time in habitats of the U.S. For purposes of the Migratory Bird Treaty Act, “take” is defined as “to pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to pursue, hunt, shoot, wound, kill, trap, capture, or collect” (50 CFR § 10.12). The Migratory Bird Treaty Act applies to migratory birds identified in 50 CFR § 10.13 (defined hereafter as “migratory birds”).

The Bald and Golden Eagle Protection Act prohibits anyone from “taking” a bald or golden eagle, including their parts, nests, or eggs, without a permit issued by the USFWS. Implementing regulations (50 CFR § 22), and USFWS guidelines as published in the National Bald Eagle Management Guidelines, provide for additional protections against “disturbances.” Similar to take, “disturb” means to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, injury to an eagle or causes either a decrease in its productivity or nest abandonment due to a substantial interference with breeding, feeding, or sheltering. A permitting process provides limited exceptions to the Bald and Golden Eagle Protection Act’s prohibitions. The USFWS has issued regulations for the permitting process in 50 CFR Part 22, which include permits for the incidental take of Bald Eagles. Such permits are only needed when avoidance of incidental take is not possible. According to federal guidelines, if
conservation measures can be implemented such that no aircraft are flown within 1,000 feet of a nest, incidental take of Bald Eagles is unlikely to occur and no permit is needed.26

4.4.2 Affected Environment

The distribution and abundance of terrestrial vegetation and wildlife species are heavily influenced by available habitat. Available habitats vary significantly across the United States and its territories even within short distances. Vegetation and wildlife resources vary widely depending on location. These resources include native and non-native plant species (vegetation) and native and non-native or migratory animal species (wildlife) and their habitats. Common, broadly classified ecosystems include deserts, grasslands, scrub, woodlands and forests, aquatic zones, wetlands, and riparian areas. Examples of broad, naturally occurring ecosystems include old growth coniferous forests in the Pacific Northwest, long-leaf pine forests of the lower eastern seaboard, and undisturbed areas within the southwestern deserts.

Because terrestrial and aquatic vegetation and wildlife vary widely depending on location, they are discussed in general terms in this PEA. Flying locations that may seek FRIA approvals are located across the United States, and providing baseline information for all vegetation and wildlife resources that could be affected by specific project sites is beyond the scope of this PEA. Existing biological resources at flying locations seeking FRIA approval are representative of biological resources across the U.S., with established flying locations throughout the country, and occupying a number of different ecoregions.27 Species of birds, mammals, reptiles, amphibians, fish, and microorganisms – and their supporting habitat – present on project sites will vary considerably from site to site. Additionally, some wildlife species are present year-round on sites whereas others are present only temporarily (e.g., migration route or nesting).

Biological resource habitats at FRIA locations vary widely from developed suburban areas with little or no natural habitat to rural areas with more undisturbed natural habitats in the immediate vicinity. The range of habitats can support a wide variety of wildlife, including amphibians, reptiles, birds, insects, and mammals. Examples of typical wildlife that may be found at flying locations include a variety of rodents (e.g., mice, squirrels, rats, beavers, voles), doves, crows, sparrows, raptors, waterfowl, bear, deer, bobcat, coyotes, turtles, frogs, lizards, snakes, butterflies, and beetles.

Habitats over which the UA would directly fly are typically already developed with existing infrastructure where habitat would range from little to no natural habitat (e.g., paved surfaces) to regularly maintained herbaceous and low shrub habitat (e.g., mowed grassy areas). These areas would likely have less wildlife diversity due to the limited habitat types compared to the areas surrounding the flying locations, which could be more diverse in habitat and wildlife. Despite the variety of habitats and wildlife at flying locations, the primary wildlife that UA affect are anticipated to be avian species, primarily birds, due to the potential direct interactions with these species while in flight.

Flying locations are typically located on private property in more rural and agricultural settings. Site boundaries are typically determined by line-of-sight limitations but also include environmental aspects, such as unprotected property or roadways. CBO flying locations (both new and existing) are also typically in more rural and agricultural settings, on private property, and away from neighborhoods and

other populated areas. Most of these flying locations are AMA clubs with existing UA operations. Educational institution flying locations (both new and existing) are typically on landscaped grounds or pavement, and typically in more rural and suburban settings. These sites are typically used by STEM classes during school hours and after school hours. Some flying locations may be established at local airports and public parks. Figures 7 through 10 are representative of the existing environment in typical flying locations that may request a FRIA approval.

Special Status Species

Special status species are those species for which state or federal agencies provide an additional level of protection by law, regulation, or policy. Included in this category are federally listed species that are protected under the ESA, species considered as candidates for such listing, bald and golden eagles (protected by the Bald and Golden Eagle Protection Act), and those species that are state-listed as threatened, endangered, or of special concern, or otherwise protected by federal or state laws. Special status species are broadly distributed throughout the United States. Special status avian species (birds, bats, flying insects) would likely be at greatest risk from UA operations. Examples of federally listed threatened and endangered avian species include the Red-cockaded Woodpecker, Piping Plover, Bachman’s Warbler, Gray Bat, and Miami Blue Butterfly. As shown in Table 1-1, the current USFWS list of threatened and endangered species includes 1,481 animal species and 939 plant species in the United States.

ESA candidate species are plants and animals for which the USFWS has sufficient information on their biological status and threats to propose them as endangered or threatened under the ESA, but for which development of a proposed listing regulation is precluded by other higher priority listing activities.

The MBTA protects 1,093 migratory birds across the United States from capture, pursuit, hunting, or removal from natural habitat. Migratory bird species include those that nest in the United States and Canada during the summer and then migrate to and from the tropical regions of Mexico, Central and South America, and the Caribbean for the non-breeding season. A variety of birds protected under the MBTA could occur in or around flying locations where UA are flown.

The USFWS also identifies birds of conservation concern (BCC), which are migratory and non-migratory bird species not already listed under the ESA that represent the highest avian conservation priorities. The BCC list is based on an assessment of several factors, including population abundance trends,

---

threats on breeding and nonbreeding grounds and size of breeding and nonbreeding ranges. A total of 134 individual bird species on the Continental United States were listed in the BCC 2021 report; just over half of these species are land birds.³⁴ Examples of BCC include the Mountain Plover, Red Knot, Reddish Egret, Eastern Whip-poor Will, and Snowy Owl.

The USFWS estimates that there are a minimum of 10 billion migratory birds that breed in North America, with fall populations on the order of 20 billion.³⁵ Alaska supports the greatest number of birds followed by Texas. Not surprisingly, states with larger land areas support a greater number of birds than smaller states. Of the just over 700 species of breeding birds known to occur in the United States, more than 400 species (over 50 percent) are passerines (also called perching birds or songbirds) and are considered migratory. These species include long-distance migrants that migrate between South and North America, for example, as well as local migrants that migrate within the boundaries of the United States. Because passerines are more likely to be found on land, the types of birds occurring at or near flying locations are predominantly passerine species.

The migratory habits of birds are highly variable among and within individual species but can be classified into several general categories.³⁶ Short distance migrants include those species that may wander locally, winter near a small portion of the breeding range, or move to different elevations, for example. Medium distance migrants may move distances of one to several states. Birds may move only as far as is needed to take advantage of local food and shelter resources. These are considered partial migrants and represent the most common types of migration patterns. Most of the North American birds, including shorebirds, some hawks, and passerines (e.g., thrushes, orioles, warblers, hummingbirds, and tanagers) are in this category. Long distance migrants, or complete migrants, include those species that breed in North America and completely leave their breeding range to spend the winter in more southern latitudes. Some long distance migrants have been known to migrate great distances; for example, the Red Knot, which breeds in the Canadian Arctic and winters in Tierra del Fuego in southern South America approximately 9,300 miles away. Another form of migration is called irruptive migration, where the patterns are not seasonally or geographically dependent but, instead, are highly dependent upon availability of food resources. Just as the distance of migration is highly variable, the routes taken can also be specific to species, subspecies and populations. Four general major flyways (Atlantic, Mississippi, Central and Pacific) have been recognized. This terminology, however, oversimplifies most avian migratory patterns. General routes of migration typically conform closely to major topographical features such as large river systems or mountain chains.

Generally, migration follows a north-south orientation, although there can be an east-west component such that elliptically shaped round-trip patterns can occur. Some species may migrate along a narrow band, particularly those species that are habitat-limited, such as shorebirds which may consistently use the same stopover points each year. For example, the Delaware Bay is renowned for its importance to hungry north-bound shorebirds that stop there to feed on horseshoe crab eggs. For many species of songbirds, migration is along a broad front where the width may be species-specific. Other avian species have converging routes where the path of migration can become constricted to align with land masses. The peninsula of New Jersey functions this way to funnel many individuals of many species together.

4.0 Affected Environment and Environmental Consequences
Bandung and modern radar studies provide much of the data used in understanding migration patterns, including location, abundance, and timing.

Geographically relevant staging (stopover) areas provide important foraging opportunities and shelter where migratory birds can rest and add fat reserves prior to continuing on their migration route. For example, many undeveloped areas along the Gulf coast are important stopover locations for the high numbers of north-bound songbirds that land there after crossing the Gulf of Mexico in the spring. They provide high quality and ecologically important habitat necessary for bird survival during migration, breeding, and wintering seasons. The locations of these areas are well known by state wildlife agencies and USFWS.

Bald Eagles occur throughout the United States, and Golden Eagles can occur throughout the United States but are more common in the western half of the country. Golden Eagles are typically found in open country in the vicinity of hills, cliffs, and bluffs; they are known to be sensitive to human activity and are known to avoid developed areas.37

4.4.3 Environmental Consequences

An evaluation of impacts to biological resources involves a comparison of current and future proposed conditions and a projection of the extent to which the alternatives might alter the current flora and fauna, migratory birds, threatened and endangered species, and designated critical habitat.

A significant impact on biological resources would occur if the USFWS or NMFS determines that the action would likely jeopardize the continued existence of a federally listed threatened or endangered species, or would result in the destruction or adverse modification of federally designated critical habitat. The FAA has not established a significance threshold for unlisted species. Factors to consider when assessing the significance of potential impacts on unlisted species include whether the action would have the potential for:

- A long-term or permanent loss of unlisted plant or wildlife species (e.g., extirpation of the species from a large project area, such as from a new commercial service airport)
- Adverse impacts on special status species or their habitats
- Substantial loss, reduction, degradation, disturbance, or fragmentation of native species’ habitats or their populations
- Adverse impacts on a species’ reproductive success rates, natural mortality rates, non-natural mortality (e.g., road kills and hunting), or ability to sustain the minimum population levels required for population maintenance

Proposed Action Alternative

The primary impacts related to FRIA approvals would include noise and visual effects, and potential collisions with wildlife. The presence of UA and humans can disturb nearby wildlife through visual and noise effects, resulting in potential displacement and altered behavioral responses. Displacement can affect normal foraging, migratory, and breeding behaviors, and could also reduce survival and productivity because animals might need to expend more energy to locate replacement habitat, which may have fewer resources and be of lower value. In addition, wildlife that is less familiar with new

habitat areas might be more susceptible to predation, which could limit survival of offspring or adults. Increased noise levels could result in fright responses (e.g., flushing or escaping) or increased communications, such as louder or more extended periods of birdsong or begging vocalizations from young birds. Significant noise occurrences could cause birds to abandon their nests with the subsequent demise of young.

Wildlife responses would vary depending on the species, the types of UA present, the UA’s proximity to wildlife and flight patterns, and weather. UA and human presence would likely cause the greatest visual and noise effects at FRIA locations and immediate surroundings. However, one study found that in most instances, small UA within four meters of birds did not cause a behavioral response.38 Based on the FAA’s understanding of the current use of flying locations, noise disruptions are short-term and temporary as these events are infrequent and short in duration. UA would not linger in a particular location for long periods of time and would move past wildlife quickly. In addition, UA are already authorized to operate at flying locations that may seek a FRIA approval, and there will be no change in the affected environment (i.e. environmental baseline) as a result of a FRIA approval. Given the infrequent and short duration that visual and noise disturbances would have at any given location, and that no permanent displacement would occur, impacts to wildlife under the proposed action alternative are not anticipated to have significant impacts.

Wildlife collisions can occur from the use of UA, which can result in injury or death of wildlife. Collisions between birds and aircraft are well documented and is an issue that airport and air transportation agencies take very seriously (due to flight safety issues); however, these collisions are estimated to account for a small percentage of all bird deaths per year, and there are very few documented collisions between UA and birds.39 40 As such, collisions from UA are not anticipated to have significant impacts on birds. If a UA collides with a flying insect, it would, in most cases, result in death of the insect. However, most insects produce high numbers of offspring multiple times during the year. Therefore, the small number of insect strikes that may occur is not likely to result in any significant impacts on flying insect species. Of all the types of aircraft in the NAS, UA are the least likely to pose a collision risk to avian species due to their much smaller size and slower speeds compared to helicopters and fixed-wing aircraft. As stated previously, operations at flying locations nearly always occur during daytime hours, and therefore, crepuscular and nocturnal wildlife (e.g., bats) are not anticipated to be affected by collisions.

Therefore, because there is no change in the environmental baseline at existing flying sites, potential impacts from FRIA approvals on wildlife would not be significant. At new flying sites requesting a FRIA approval, the FAA will conduct further site-specific analysis to determine whether any wildlife or critical habitat could be affected.

Special Status Species

Impacts on threatened and endangered species were classified using the following terminology, as defined under the ESA:

4.0 Affected Environment and Environmental Consequences

- **No effect** – would be determined if a proposed action would not affect a listed species or designated critical habitat.

- **May affect/not likely to adversely affect** – would be determined if impacts on listed species are discountable (i.e., extremely unlikely to occur and not able to be meaningfully measured, detected, or evaluated) or completely beneficial.

- **May affect/likely to adversely affect** – would be determined when an adverse effect on a listed species occurs as a direct or indirect result of proposed actions and the effect is neither discountable nor completely beneficial.

- **Likely to jeopardize proposed species/adversely modify critical habitat** – would be determined if the USFWS identified situations in which actions could jeopardize the continued existence of a listed species or adversely modify habitat critical to a species within or outside of the project area.

Impact types and mechanisms on threatened and endangered species would be the same as those described above for wildlife, except threatened and endangered species may be more sensitive or vulnerable to impacts. However, it is anticipated that potential visual, noise, and collision impacts would not be significant or result in population-level effects for the same reasons described above.

At both existing and new FRIA locations, impacts to threatened and endangered species and critical habitat would be expected to stay the same once a FRIA is approved, as there would be no real change in the environmental baseline. Therefore, the FAA has determined that FRIA approvals would have no effect on threatened and endangered species.

In addition, UA operators at CBO and educational institution locations would be expected to be aware of any known sensitive wildlife and habitat within the area, and avoid such locations at times when it could disturb protected species. UA operators at FRIA locations would be required to comply with all federal, state, and local permitting requirements for the protection of special status species (e.g., Bald and Golden Eagle Protection Act).

During the FRIA application approval process, if the FAA determines that the establishment of a FRIA is likely to jeopardize the continued existence of proposed threatened and endangered species or result in destruction or adverse modification of proposed critical habitats, the FAA would coordinate with the appropriate USFWS office, and a tiered environmental assessment (EA) could be required if effects to threatened and endangered species may occur, or if the destruction or adverse modification of habitat cannot be avoided. Resource avoidance for specific FRIA approvals may occur for resources such as critical habitat for threatened or endangered species, special habitat management units, sensitive species areas, and important breeding, roosting or foraging areas. Buffer distances are typically established through consultation with the regulatory agency to avoid an ‘incidental take’ by disturbance or harassment of protected species, such as those protected under ESA and the Bald and Golden Eagle Protection Act.

Federally listed endangered and threatened species, state-listed species, and migratory birds may occur at FRIA sites. However, since the baseline affected environment includes existing UA operations, there will be little, if any, change to analyze for the affected environment. Additionally, there will be no changes to terrestrial or aquatic environments. UA operations at these flying locations will be within a relatively small limited operating area and are not expected to impact critical lifecycles of wildlife species or their ability to survive.
The FAA’s analysis finds that the proposed action is not expected to cause any of the following impacts:

- A long-term or permanent loss of unlisted plant or wildlife species, i.e., extirpation of the species from a large project area;
- Adverse impacts to special status species (e.g., state species of concern, species proposed for listing, migratory birds, bald and golden eagles) or their habitats;
- Substantial loss, reduction, degradation, disturbance, or fragmentation of native species’ habitats or their populations; or
- Adverse impacts on a species’ reproductive success rates, natural mortality rates, non-natural mortality (e.g., road kills and hunting), or ability to sustain the minimum population levels required.

**No Action Alternative**

Under the no action alternative, no new impacts will occur to vegetation/flora, wildlife/fauna and rare, threatened, and/or endangered species. The no action alternative will not result in any construction-related habitat disturbances. The no action alternative assumes that a FRIA would not be approved, but that UA operators may still fly at the proposed location using Remote ID broadcast technology. If a FRIA application is rejected, no new effects to threatened and endangered species would occur. Consequently, there will be no new impacts to biological resources as a result of the no action alternative.

### 4.5 Climate

#### 4.5.1 Regulatory Setting

FAA Order 1050.1F requires consideration of potential climate impacts. The FAA has not established a significance threshold for climate effects, and has not identified any factors to consider in making a significance determination for greenhouse gas (GHG) emissions.

#### 4.5.2 Affected Environment

The affected environment for GHG emissions is the global climate because the incremental contribution to global GHGs from each instance when the FAA approves a proposed action cannot be accurately translated into the potential effect it might have on global climate change or the local or regional effects resulting from that incremental contribution. Furthermore, the FAA does not expect the direct or indirect effects from the proposed action to contribute to the temperature and weather effects of global climate change as compared to the overall effect of the aviation sector on global climate change.

#### 4.5.3 Environmental Consequences

The FAA’s Air Quality Assessment for FRIAs (Appendix A) calculated annual emissions from each UA, including CO2 emissions. The analysis is based on direct emissions associated with UA operations. Indirect emissions associated with automobile trips were not included; however, emissions associated with these trips are not expected to significantly affect the results and conclusions in the analysis.

Currently, electric engines are the primary type of propulsion used at UA flying locations, and that is expected to remain true for locations seeking a FRIA establishment. UAs with gas or turbine engines, which emit small quantities of GHGs, may also operate within FRIAs; however, the existence and
operation of such UA are not expected to be substantial. UA with combustion engines are likely to occur at lower activity levels than electric-powered UA as they tend to be less common.

Proposed Action Alternative

The Air Quality Assessment for FRIAs shows that the emissions would be extremely small in the context of regional, national, and global emissions. The proposed action alternative would not result in substantive changes to activity levels and their associated GHG emissions at new and existing flying locations. Therefore, GHG emissions from UA operations at new and existing FRIA locations would not cause significant impacts to climate.

No Action Alternative

The no action alternative would not result in substantive changes to activity levels and their associated GHG emissions at new and existing flying locations. The no action alternative assumes that a FRIA would not be approved, but that UA operators may still fly at the location using Remote ID broadcast technology. If a FRIA application is rejected, no new substantial GHG emissions are expected to occur. Consequently, there will be no new impacts to climate as a result of the no action alternative.

4.6 Department of Transportation Act, Section 4(f) Resources

4.6.1 Regulatory Setting

Section 4(f) of the U.S. Department of Transportation (DOT) Act of 1966 (now codified at 49 U.S.C. § 303) protects significant publicly owned and accessible parks, recreational areas, wildlife and waterfowl refuges, and public and private historic sites. Section 4(f) provides that the Secretary of Transportation may approve a transportation program or project requiring the use of publicly owned land of a public park, recreation area, or wildlife or waterfowl refuge of national, state, or local significance, or land of an historic site of national, state, or local significance, only if there is no feasible and prudent alternative to using that land and the program or project includes all possible planning to minimize harm resulting from the use.

A Section 4(f) use would occur if the proposed action would involve a physical use of Section 4(f) property through purchase of land or a permanent easement, physical occupation of a portion or all of the property, or alteration of structures or facilities on the property. Another type of physical use, known as temporary occupancy, results when a transportation project results in activities that require a temporary easement, right-of-entry, project construction, or another short-term arrangement involving a Section 4(f) property. A temporary occupancy is considered a Section 4(f) use unless all the conditions listed in Appendix B, Paragraph 2.2.1 of FAA Order 1050.1F and the Section 4(f) regulations at 23 CFR 773.13(d) are satisfied:

- Duration must be temporary, i.e., less than or equal to the time needed for construction of the project, and there should be no change in ownership of the land;
- Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal;
- There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis;
• The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project; and

• There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) resource regarding the above conditions.

A physical **use** may be considered **de minimis** if, after considering avoidance, minimization, mitigation, and enhancement measures, the result is either 1) a determination that the project would not adversely affect the activities, features, or attributes qualifying a park, recreation area, or wildlife or waterfowl refuge for protection under Section 4(f); or 2) a Section 106 **finding of no adverse effect or no historic properties affected**. Before the FAA may finalize a determination that a physical use is **de minimis**, the official(s) with jurisdiction must concur in writing that the project will not adversely affect the activities, features, or attributes that make the property eligible for Section 4(f) protection.

**Use**, within the meaning of Section 4(f), includes not only the physical taking of such property, but also **constructive use**. The concept of **constructive use** is that a project that involves no actual physical use of a Section 4(f) property via permanent incorporation or **temporary occupancy**, but may still, by means of noise, air pollution, water pollution, or other proximity-related impacts, substantially impair important features, activities, or attributes associated with the Section 4(f) property. **Substantial impairment** occurs only when the protected activities, features, or attributes of the Section 4(f) property that contribute to its purpose and significance are substantially diminished. This means that the value of the Section 4(f) property, in terms of its prior purpose and significance, is substantially reduced or lost.

Procedural requirements for complying with Section 4(f) are set forth in DOT Order 5610.1C, **Procedures for Considering Environmental Impacts**. The FAA also uses Federal Highway Administration (FHWA) regulations (23 CFR part 774) and FHWA guidance (e.g., Section 4(f) Policy Paper) when assessing potential impacts on Section 4(f) properties. These requirements are not binding on the FAA; however, the FAA may use them as guidance to the extent relevant to FAA projects. More information about DOT Act, Section 4(f) can be found in Chapter 5 of the FAA Order 1050.1F Desk Reference.41

### 4.6.2 Affected Environment

Section 4(f) properties include parks and recreational areas of national, state, or local significance that are both publicly owned and open to the public; publicly owned wildlife refuges of national, state, or local significance that are open to the public; and historic sites of national, state, or local significance in public or private ownership regardless of whether they are open to the public. Due to the nationwide scope of the proposed action, Section 4(f) properties likely are located in the study area.

The FAA has determined that some existing flying locations have been established in state and local public parks, although it is assumed that these operators have approval from the park authority in order to conduct their activities within the park. UA flying activities in public parks would generally be located away from other activities or protected areas within the park.

The FAA has not found any existing flying locations at historic sites or wildlife refuges, and this would not be expected to change in the future since the relevant authorities overseeing historic sites and wildlife refuges are not likely to approve a UA flying location at these types of properties.

---

4.6.3 Environmental Consequences

Impacts on Section 4(f) properties would be significant if the proposed action involves more than a minimal physical use of a Section 4(f) resource or constitutes a constructive use based on an FAA determination that the project would substantially impair the Section 4(f) resource.

Proposed Action Alternative

The FAA has determined that infrequent UA overflights as described in the proposed action will not cause substantial impairment to Section 4(f) resources that could occur in the study area and would not be considered a constructive use of any Section 4(f) resource. There will be no physical use of Section 4(f) resources. Noise and visual effects from occasional UA overflights are not expected to diminish the activities, features or attributes of the resources that contribute to their significance or enjoyment. Additionally, based on the FAA’s analysis, there will be no change in the environmental baseline as a result of FRIA approvals. Therefore, the proposed action would not result in significant impacts to Section 4(f) resources.

No Action Alternative

Under the no action alternative, impacts to Section 4(f) resources would be expected to stay the same. The no action alternative is not expected to result in significant impacts to Section 4(f) properties from UA use because, if a FRIA application is denied, the CBO or educational institution would be likely to continue using the flying location for UA operations (only with the use of Remote ID broadcasting). As there would be no apparent change in the environmental baseline, there would be no significant impacts as a result of the no action alternative.

4.7 Noise and Noise-Compatible Land Use

4.7.1 Regulatory Setting

Aircraft noise is often the most noticeable environmental effect associated with any aviation project. Several federal laws, including the Aviation Safety and Noise Abatement Act of 1979, as amended (49 U.S.C. §§ 47501-47507) regulate aircraft noise. Through 14 CFR Part 36, the FAA regulates noise from aircraft.

FAA Order 1050.1F, Appendix B, Paragraph B-1.3 requires the FAA to identify the location and number of noise sensitive areas that could be significantly impacted by aircraft noise. As defined in FAA Order 1050.1F, Paragraph 11-5b, a noise sensitive area is “[a]n area where noise interferes with normal activities associated with its use. Normally, noise sensitive areas include residential, educational, health, and religious structures and sites, and parks, recreational areas, areas with wilderness characteristics, wildlife refuges, and cultural and historical sites.”

Sound is measured in terms of the decibel (dB), which is the ratio between the sound pressure of the sound source and 20 micropascals, which is nominally the threshold of human hearing. Various weighting schemes have been developed to collapse a frequency spectrum into a single dB value. The A-weighted decibel, or dBA, corresponds to human hearing accounting for the higher sensitivity in the mid-range frequencies.

To comply with NEPA requirements, the FAA has issued requirements for assessing aircraft noise in FAA Order 1050.1F, Appendix B. FAA’s primary noise metric for aviation noise analysis is the yearly Day-Night Average Sound Level (DNL) metric. The DNL metric is a single value representing the logarithmically
average aircraft sound level at a location over a 24-hour period, with a 10 dB adjustment added to those noise events occurring from 10:00 p.m. and up to 7:00 a.m. the following morning. A significant noise impact is defined in Order 1050.1F as an increase in noise of DNL 1.5 dB or more at or above DNL 65 dB noise exposure or a noise exposure at or above the 65 dB level due to a DNL 1.5 dB or greater increase.

4.7.2 Affected Environment

The ambient (or background) sound level in the study area varies and depends on the current land use at and in the immediate vicinity of the proposed FRIA location. For example, the ambient sound level in a rural area is lower than the ambient sound level near a highway or on the grounds of an airport. Existing sound sources in the study area range from natural sounds (wind, animal calls, thunder) to anthropogenic sources associated with commercial and residential land uses (e.g., vehicles, farm equipment, lawn mowers, railroads, construction equipment, aircraft).

Sources and levels of noise at existing UA flying locations are representative of rural and suburban areas across the nation. Existing sources of noise that can be heard around sites would include road traffic, rail traffic, aircraft overflights, air cooling and heating systems, back-up generators, manufacturing, home activities and natural sounds such as bird vocalizations, running water, and wind. On a daily basis, suburban areas are more likely to exhibit higher ambient noise levels resulting from highway traffic (70 to 90 A-weighted decibels (dBA)), construction noise (90 to 120 dBA), and outdoor conversations (e.g., small/large groups of people) (60 to 90 dBA).

Figure 7 shows typical existing ambient DNL ranging from a small-town residential area to a downtown city. According to the figure, which was produced by the FAA, many of the remote areas in the study area are expected to have a DNL less than 50 dBA, while urban areas are expected to have a DNL as high as 80 dBA.

4.7.3 Environmental Consequences

Human perception of noise depends on a number of factors, including overall noise level, number of noise events, the extent of audibility above the ambient sound level, and acoustic frequency content.

---

42 A-weighting approximates the frequency response of human hearing.
(pitch). UA noise generally has high acoustic frequency content, which can often be more discernable from other typical noise sources.

Noise impacts would be significant if the action would increase noise by DNL 1.5 dB or more for a noise-sensitive area that is exposed to noise at or above the DNL 65 dB noise exposure level, or that will be exposed at or above the DNL 65 dB level due to a DNL 1.5 dB or greater increase, when compared to the no action alternative for the same timeframe. For example, an increase from DNL 65.5 dB to 67 dB is considered a significant impact, as is an increase from DNL 63.5 dB to 65 dB.

**Proposed Action Alternative**

To ensure that noise would not cause a significant impact to any residential land use or other noise sensitive resources within or adjacent to flying locations seeking a FRIA approval, the FAA initiated an analysis of the potential noise exposure that could result from the proposed action. The noise analysis methodology detailed in Appendix B was used to calculate DNL for various operational counts and aircraft types.

The number of flight events and associated flight time required for UA to generate noise levels at or above DNL 65 dB was estimated using available noise measurement data for small (i.e., under 55 pounds) fixed-wing and multicopter UA. The results of the analysis show that, for the measured UA, the number of Average Annual Day (AAD) flight events and associated flight times required to produce DNL 65 dB at a fixed receiver location within a flight area is generally much higher than what would be likely or practically possible to occur in foreseeable real-world conditions.

Collection of additional noise data and further noise analysis may be warranted to evaluate the potential for noise exposure impacts at flying locations expected to have a substantial portion of flight activity from helicopter UA and/or multicopters with gas or turbine engines, and for flying locations expected to have frequent activity by any UA heavier than 55 pounds. However, significant noise impacts are unlikely to result in any case given that the FAA anticipates that the implementation of the Remote ID rule, and FRIAs to accommodate operation of UA without remote ID, to have a very little effect on the overall level of activity occurring at existing or new flying locations.

Based on expected UA operations at proposed FRIA flying locations, which typically involves one UA in the air at a time, with operations lasting a few hours per day up to seven days per week, the proposed action’s estimated DNL is less than DNL 65 dB (see the Noise Analysis Report in Appendix B). Additionally, the proposed action would not increase noise exposure levels by DNL 1.5 dB within a DNL 65 dB noise exposure corridor. Therefore, the proposed action would not result in significant noise impacts.

**No Action Alternative**

Under the no action alternative, noise levels will continue at current levels at existing sites. No localized or regional changes to noise are expected. Some flying locations where a FRIA application is rejected may see an overall noise reduction under the no action alternative, as some remote pilots could move to approved FRIA locations when they wish to fly without Remote ID broadcasting. The no action alternative is not expected to result in significant noise impacts given the average sound levels of the UA, the short duration of operations, and the number of daily operations at any given flying location. Consequently, impacts to noise as a result of the no action alternative would not result in significant noise impacts.
4.8 Visual Effects

4.8.1 Regulatory Setting

Visual resources and visual character impacts deal with the extent to which the proposed action would result in visual impacts to resources in the operating area. Visual impacts can be difficult to define and evaluate because the analysis is generally subjective, but are normally related to the extent that the proposed action would contrast with, or detract from, the visual resources and/or the visual character of the existing environment. In this case, visual effects would be limited to the introduction of a visual intrusion – a UA in flight – which could be out of character with the landscapes where proposed FRIA sites are located.

Visual resources include buildings, sites, traditional cultural properties, and other natural or manmade landscape features that are visually important or have unique characteristics. In unique circumstances, the nighttime sky may be considered a visual resource. Visual character refers to the overall visual makeup of the existing environment where the project would be located. For example, areas near densely populated locations generally have a visual character that could be defined as urban, whereas less developed areas could have a visual character defined by the surrounding landscape features, such as open grass fields, forests, mountains, and deserts.

Some visual resources are protected under federal, state, or local regulations. Protected visual resources generally include, but are not limited to, federal, state, or local scenic roadways/byways; National Scenic Areas; scenic easements; trails protected under the National Trails System Act or similar state or local regulations; biological resources; and features protected under other federal, state, or local regulations. More information about visual resources and visual effects can be found in Chapter 13 of the FAA Order 1050.1F Desk Reference.43

4.8.2 Affected Environment

The affected environment includes a variety of urban, suburban, and rural areas, including areas that may have sensitive visual resources. The immediate affected environment, however, is the common viewscape of the established flying location and immediate surroundings where UA operations already occur, resulting in similar direct visual environments nationwide.

Visual and aesthetic resources are the natural and man-made features that constitute an area’s visual character. They include the landscape character (what is seen), visual sensitivity (human preferences and values regarding what is seen), scenic integrity (degree of intactness and wholeness in landscape character), and landscape visibility (relative distances of seen areas) of a geographically defined viewshed. Visual resources generally refer to the urban environment, whereas aesthetic resources typically refer to natural and scenic areas. The visual and aesthetic characteristics of a location depend on whether the area is a remote, rural, or urban setting. In a remote or rural setting, the landscape tends to be dominated by naturally occurring landforms and vegetation. Although naturally occurring visual resources dominate rural areas, some signs of human activity are likely to be present and may also contribute to the aesthetics. Examples include houses, agricultural fields, fences, barns, highways, communications towers, power lines, and lighthouses. Remote areas may have no visible man-made structures. Within an urban setting, natural features that may be present include parks and other green spaces, waterfalls, and ponds.

Effects to aesthetic and visual resources deal broadly with the extent to which development contrasts with the existing environment, architecture, historic or cultural setting, or land use. Evaluating the visual and aesthetic qualities of an area is a subjective process because the value an observer places on specific landscape features varies depending upon the values and attitudes of the observer. Visual intrusions may also have an impact on some traditional cultural practices. Regardless of the subjective nature of assessing visual and aesthetic qualities of an area, landforms, water surfaces, vegetation, and man-made features can generally be considered characteristic of an area if they are inherent to the composition and function of the landscape.

4.8.3 Environmental Consequences

The FAA has not established a significance threshold for light emissions or visual resources/visual character. Factors to consider when assessing the significance of potential visual effects include the degree to which the action would have the potential to:

- Create annoyance or interfere with normal activities from light emissions
- Affect the visual character of the area due to the light emissions, including the importance, uniqueness, and aesthetic value of the affected visual resources
- Affect the nature of the visual character of the area, including the importance, uniqueness, and aesthetic value of the affected visual resources
- Contrast with the visual resources and/or visual character in the study area
- Block or obstruct the views of visual resources, including whether these resources would still be viewable from other locations

**Proposed Action Alternative**

Under the proposed action, UA operations would generally occur during the daytime and therefore would not involve light emissions. The proposed action would not result in construction or a change in land use and would not affect the visual character of flying locations and adjacent properties. Due to the relatively small size of UA, views from the ground would likely be possible within half a mile, and may be obscured by trees, houses, or other structures due to the low altitudes where the UA operate. Additionally, since UA are already authorized to fly in these locations, there would be no change in the environmental baseline as a result of FRIA approvals. Therefore, no increased impacts to visual resources would result from the proposed action. Any impacts to visual resources under the proposed action would be similar to the no action alternative. Therefore, the proposed action would not result in significant visual effects.

**No Action Alternative**

Under the no action alternative, impacts to visual resources would be expected to stay the same. The no action alternative is not expected to result in significant impacts to visual resources or visual character from UA operations and vehicle use or foot traffic. Activities at flying locations generally take place during daytime hours and would not result in significant light emissions impacts.
4.9 Summary of Potential Impacts under the Proposed Action

Table 4-1 Summary of Potential Impacts

<table>
<thead>
<tr>
<th>Environmental Impact Category</th>
<th>Significance Threshold</th>
<th>Anticipated Environmental Impacts</th>
</tr>
</thead>
</table>
| **Air Quality**               | The action would cause pollutant concentrations to exceed one or more of the NAAQS, as established by the Environmental Protection Agency under the Clean Air Act, for any of the time periods analyzed, or to increase the frequency or severity of any such existing violations. | The FAA’s analysis finds that approving FRIAs at UA flying locations would not:  
• Cause or contribute to any new violation of a NAAQS;  
• Increase the frequency or severity of any existing violation; or  
• Delay the timely attainment of any standard, interim emission reduction, or other milestone. |
| **Biological Resources (including fish, wildlife, and plants)** | The USFWS or NMFS determines that the action would be likely to jeopardize the continued existence of a federally listed threatened or endangered species, or would result in the destruction or adverse modification of federally designated critical habitat. The FAA has not established a significance threshold for non-listed species. | The FAA’s analysis finds that approving FRIAs at existing UA flying locations would not cause:  
• A long-term or permanent loss of unlisted plant or wildlife species, i.e., extirpation of the species from a large project area (e.g., a new commercial service airport);  
• Adverse impacts to special status species (e.g., state species of concern, species proposed for listing, migratory birds, bald and golden eagles) or their habitats;  
• Substantial loss, reduction, degradation, disturbance, or fragmentation of native species’ habitats or their populations; or  
• Adverse impacts on a species’ reproductive success rates, natural mortality rates, non-natural mortality (e.g., road kills and hunting), or ability to sustain the minimum population levels required for population maintenance.  
FRIA applications for new UA flying locations will require further analysis to confirm that there will be no significant impacts to biological resources at those locations. |

<td><strong>Noise and Noise-Compatible Land Use</strong></td>
<td>The action would increase noise by DNL 1.5 dB or more for a noise sensitive area that is exposed to noise at or above the DNL 65 dB noise exposure level, or that will be exposed at or above the DNL 65 dB level due to a DNL 1.5 dB or greater increase, when compared to the no action alternative for the same timeframe. For example, an increase from DNL 65.5 dB to 67 dB is considered a significant impact, as is an increase from DNL 63.5 dB to 65 dB.</td>
<td>The FAA’s analysis finds that noise levels at existing UA flying locations, including those seeking FRIA approvals, will not increase by DNL 1.5 dB or more for a noise sensitive area that is exposed to noise at or above the DNL 65 dB noise exposure level, or that will be exposed at or above the DNL 65 dB level due to a DNL 1.5 dB or greater increase, when compared to the no action alternative for the same timeframe. FRIA applications for new UA flying locations will require further analysis to confirm that there will be no significant noise impacts at those locations.</td>
</tr>
<tr>
<td><strong>Visual Resources</strong></td>
<td>The FAA has not established a significance threshold for visual effects. Factors the FAA considers in assessing significant impacts include the degree to which the action would have the potential to: (1) affect the nature of the visual character of the area, including the importance, uniqueness, and aesthetic value of the affected visual resources; (2) contrast with the visual resources and/or visual character in the study area; or (3) block or obstruct the views of visual resources, including whether these resources would still be viewable from other locations.</td>
<td>The FAA’s analysis finds that FRIA approvals will not: • Create annoyance or interfere with normal activities from light emissions; • Affect the visual character of the area due to the light emissions, including the importance, uniqueness, and aesthetic value of the affected visual resources; • Affect the nature of the visual character of the area, including the importance, uniqueness, and aesthetic value of the affected visual resources; • Contrast with the visual resources and/or visual character in the study area; or • Block or obstruct the views of visual resources, including whether these resources would still be viewable from other locations.</td>
</tr>
</tbody>
</table>
5.0 CUMULATIVE IMPACTS

The CEQ NEPA-implementing regulations define cumulative effects as “effects on the environment that result from the incremental effects of the action when added to the effects of other past, present, and reasonably foreseeable actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative effects can result from individually minor but collectively significant actions taking place over a period of time.” (40 CFR § 1508.1(g)(3)) As discussed in Chapter 4, it is anticipated that the proposed action will not impact several environmental impact categories (see Section 4.1) and will result in minimal impacts on others. Under the proposed action, UA operations would occur infrequently and typically at locations where flying locations already exist and where those operations are not expected to change as compared to the no action alternative. The proposed action’s potential to contribute to cumulative impacts on any resource is limited to any other operations that might occur at the location at the same time the UA are flying. Given the nature of the proposed action, the locations where UA operations would occur, and the minimal expected impacts of the proposed action, there is no potential for the proposed action, when combined with other past, present, or reasonably foreseeable actions, to result in cumulative impacts.

1 Introduction and Background

The Federal Aviation Administration (FAA) is implementing Subpart C, FAA-Recognized Identification Areas (FRIA), of Title 14 of the Code of Federal Regulations (CFR) Part 89, Remote Identification of Unmanned Aircraft (Remote ID Rule) 86 FR 4390 (Jan. 15, 2021). Subpart C established a path through which eligible entities may seek approval from the FAA to establish a FRIA. After the Remote ID Rule is fully effective, unmanned aircraft (UA) equipped with remote identification technology can continue to operate nationally under existing regulations. All UA pilots required to register their aircraft must operate in accordance with the Remote ID Rule beginning September 16, 2023. The Remote ID Rule requires UA to be equipped with remote identification at locations outside of FRIA locations.

This document describes the methodology used to evaluate the potential for air quality impacts from the operation of UA within FRIAs at both existing and new flying locations.

Conservative assumptions and FAA and United States Environmental Protection Agency (EPA) methodologies were used to determine potential air quality impacts against EPA significance emission thresholds. An emissions analysis was conducted based on a representative set of recreational UA and applying EPA emission factors for similar-type engines, assuming conservative (e.g., longer duration) flight times. Annual emissions from each UA were compared to worst-case EPA de minimis thresholds for each criteria pollutant at both new and existing flying locations. The analysis is based on direct emissions associated with UA operations. Indirect emissions associated with automobile trips were not included; however, emissions associated with these trips are not expected to significantly affect the results and conclusions in the analysis.

2 Regulatory

Under the National Environmental Policy Act (NEPA), federal agencies are required to conduct an environmental review of “proposed major Federal actions significantly affecting the quality of the human environment” and consider alternatives to the proposed actions, including the no action alternative (42 U.S.C. § 4332(c)). According to the FAA’s NEPA implementing guidance (FAA Order 1050.1F), impacts to air quality must be considered as part of the environmental analysis under NEPA. Potential effects of the Proposed Action are evaluated against the National Ambient Air Quality Standards (NAAQS), as promulgated by the EPA under the federal Clean Air Act (CAA).

2.1 National Ambient Air Quality Standards

The EPA currently regulates six criteria pollutants: ozone (O₃), carbon monoxide (CO), nitrogen dioxide (NO₂), sulfur dioxide (SO₂), particulate matter (PM), and lead (Pb). Particulate matter is divided into two particle size categories: coarse particles with a diameter less than 10 micrometers (PM₁₀) and fine particles with a diameter of less than 2.5 micrometers (PM₂.₅).

Table 2-1 shows the primary and secondary NAAQS for the criteria pollutants. Section 176(c) of the CAA states that federal agencies cannot engage, support, or provide financial assistance for licensing, permitting, or approving any project that could cause or contribute to the severity and/or number of violations of the NAAQS, or could inhibit the expeditious attainment of these standards.

</table>

Notes:

1. For PM₁₀, the 24-hour standard not to be exceeded more than once per year on average over 3 years. For PM₂.₅, the 24-hour standard is attained when 98% of the daily concentrations, averaged over 3 years, are equal to or are less than the standard.

2. To attain this standard, the 3-year average of the 98th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 0.100 ppm (effective January 22, 2010).

3. Final rule signed June 2, 2010. To attain this standard, the 3-year average of the 99th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 75 ppb.

4. EPA updated the NAAQS for O₃ to strengthen the primary 8-hour standard to 0.07 ppm on October 1, 2015. An area will meet the standard if the fourth-highest maximum daily 8-hour ozone concentration per year, averaged over 3 years is equal to or less than 70 ppb.

### 2.2 EPA-Designated Attainment Status

The standards in Table 2-1 apply to the concentration of a pollutant in outdoor ambient air. If the air quality in a geographic area is equal to or better than the national standard, the EPA will typically designate the region as an “attainment area.” An area where air quality does not meet the national standard is typically designated by the EPA as a “nonattainment area.” Once the air quality in a nonattainment area improves to the point where it meets the standards and the additional requirements outlined in the CAA, the EPA can redesignate the area to attainment upon approval of a Maintenance Plan, and these areas are then referred to as “maintenance areas.” Each state is required to prepare a State Implementation Plan (SIP) that outlines measures that regions within the state will implement to attain the applicable air quality standard in nonattainment areas for applicable criteria air pollutants, and to maintain compliance with the applicable air quality standard in maintenance areas. The status and severity of pollutant concentrations in a particular area will impact the types of measures a state must take to reach attainment with the NAAQS. The EPA must review and approve each state’s SIP to ensure the proposed measures are sufficient to either attain or maintain compliance with the NAAQS within a set period of time.
The Clean Air Act Amendments (CAAA) of 1990 require states to make recommendations to the EPA regarding the attainment status of all areas within their borders when the EPA finalizes an update to any NAAQS. Under its CAAA authority, the EPA further classifies nonattainment areas for some pollutants – such as ozone – based on the severity of the NAAQS violation as marginal, moderate, serious, severe, and extreme. To further improve the nation’s air quality, the EPA lowered the ozone standard in 2015 to 0.070 parts per million (ppm). These attainment designations are important for comparing to appropriate EPA significance thresholds.

2.3 EPA Significant Thresholds

As provided in FAA Order 1050.1F, an action would cause a significant air quality impact if pollutant concentrations would exceed one or more of the NAAQS established by the EPA under the CAA, for any of the time periods analyzed, or would increase the frequency or severity of any such existing violations. Additionally, the CAA requires federal agencies such as the FAA to ensure their actions conform to the appropriate SIP. Conformity requires that a project or action adheres to the SIP’s purpose of eliminating or reducing the severity and number of violations of the NAAQS and achieving expeditious attainment of such standards. Federally funded and approved actions at airports are subject to the EPA’s general conformity regulations. Revisions to the General Conformity Rule are codified under 40 CFR Parts 51 and 93, Subpart W, Revisions to the General Conformity Regulations, Final Rule (April 2010). The General Conformity Rule applies to all federal actions except for certain highway and transit programs which must comply with the Transportation Conformity Plans (40 CFR Part 93, Subpart A).

The General Conformity Rule includes annual emissions thresholds for nonattainment and maintenance areas that trigger the need for a General Conformity determination and defines projects that are typically excluded from General Conformity requirements. If General Conformity applies, an applicability analysis is performed to determine if a General Conformity Determination is required to demonstrate that the Proposed Action conforms to the approved SIP(s). A conformity determination is required if the total direct and indirect pollutant emissions resulting from a project are above the de minimis emissions threshold levels specified in the conformity regulations. The de minimis thresholds represent emission quantities of a NAAQS-regulated pollutant, or its applicable precursors, over which a proposed action in a nonattainment or maintenance area may cause or contribute to a new or continued violation of the NAAQS. A conformity determination is not required if the differences in emissions between the Proposed Action and the No Action Alternative are below the applicable de minimis emission threshold levels, or if the Proposed Action is exempt or included in the FAA list of “presumed to conform activities.”

The EPA de minimis emission thresholds for maintenance and nonattainment areas are summarized in Table 2-2a and Table 2-2b.

Note 1: 40 CFR 93.153(b)(2) - For purposes of paragraph (b) of this section these rates apply in maintenance areas

As noted in Table 2-2a and Table 2-2b, pollutants' designated attainment does not have EPA de minimis thresholds. Therefore, as a conservative assumption for this analysis, the worst-case (i.e., lowest) EPA de minimis thresholds were used for each pollutant when comparing the emissions from UA engines in order to determine significance. The EPA worst-case de minimis thresholds to determine significant impacts under NEPA for each pollutant are shown in Table 2-3. The de minimis thresholds represent emission quantities of a NAAQS-regulated pollutant, or its applicable precursors, over which a proposed action in a nonattainment or maintenance area may cause or contribute to a new or continued violation of the NAAQS. In accordance with the FAA Environmental Desk Reference for Airport Actions, the Proposed Action can be determined to “not cause a significant air quality impact, since it is unlikely the
pollutant concentration analyzed would exceed a NAAQS.” This is demonstrated by showing the Proposed Action emissions would not exceed a *de minimis* pollutant emission threshold.

3 Methodology

The methodology and assumptions used to estimate the UA engine model emissions for comparison to EPA de minimis thresholds to determine significant air quality impacts from the operation of UA within FRIA at both existing and new flying locations is discussed in this section.

An internet search was conducted for various UA engines on the market, noting sizes and performance, along with engine speeds (rotations per minute). In lieu of model specific emission factors to estimate emissions, the latest version of the EPA MOVES model (Version 3.0.4)³ was used to develop emission factors for similar-size engines. These engines were compared to equipment listed in the EPA MOVES nonroad database, and the Lawn/Garden category was found to be the most representative in terms of engine size and fuel usage. The EPA MOVES model was utilized since it is an approved emission model for similar engine types commonly used in UA, and it is used as an approved emission model for FAA NEPA analyses⁴ for computing nonroad (e.g., chainsaws, lawn mower engines) emissions.

A second internet search was conducted to determine engine specifications for actual lawn and garden equipment on the market today. Based on this search, the following subset of the Lawn/Garden category appears to be a representative database of typical commonly used model aircraft engines:

- Lawn Mowers (residential)
- Lawn Mowers (commercial)
- Rotary Tillers < 6 horsepower (hp) (residential)
- Rotary Tillers < 6 hp (commercial)
- Chain Saws < 6 hp (residential)
- Chain Saws < 6 hp (commercial)
- Trimmers/Edgers/Brush Cutter (residential)
- Trimmers/Edgers/Brush Cutter (commercial)
- Leaf blowers/Vacuums (residential)
- Leaf blowers/Vacuums (commercial)
- Rear Engine Riding Mowers (residential)
- Rear Engine Riding Mowers (commercial)
- Front Mowers (commercial)
- Shredders < 6 hp (commercial)

The specifications for actual lawn and garden equipment were compared to engine specifications found for several various-sized UA engine specifications. For each UA engine, a lawn/garden engine with similar specifications was selected to be utilized in the analysis. Table 3-1 shows the UA model engine and MOVES representative equipment that were used in the analysis based on that comparison.

</tbody>
</table>

For this analysis, the assumption was made that the engines utilized gasoline as fuel, which is common in both lawn and garden equipment and UA engines.

In order to run the MOVES model, it was required to select a geographic area. Based on a review of the Academy of Model Aeronautics (AMA) club database, the Palm Beach Radio Control Association (based out of Palm Beach County, Florida) has the most members and is currently active. Therefore, the MOVES representative equipment for each model engine type used to develop the emission factors incorporates county-level data representative of Palm Beach County, Florida for criteria pollutants/precursors. A representative existing year of 2022 was assumed for MOVES and a conservative load factor of 1 (assumes a constant full throttle while operating) was assumed for this analysis.

Emissions were estimated using MOVES emission factors in grams per horsepower (g/hp-hour) for each engine type and were applied to the equipment size in hp and load factor. In order to estimate worst-case emissions, a hypothetical UA engine using an amalgamation of worst-case emissions factors across all pollutants was used. Table 3-2 shows the MOVES emissions factors by engine (with their corresponding representative equipment from MOVES), along with the emissions factors utilized for a hypothetical worst-case engine for each pollutant.

Worst Case Engine Emissions Factors 271.680 5.522 0.005 8.075 7.429 51.406 1062.673

Because the annual hours of flight at any location (with or without a designated FRIA) cannot be exactly determined, a unit-analysis was conducted to see how many hours per year it would take to exceed the worst-case EPA *de minimis* thresholds using the emissions factors for a worst-case hypothetical engine.

The emissions for each model engine type were computed using the following equation:

\[
\text{Aircraft Model Engine Type emissions (tons per year (TPY))} = \text{emission factor (grams per hp-hr)} \times \text{size (hp)} \times \text{load factor} \times \text{hours per year} \times \left(\frac{1 \text{ pound}}{453.6 \text{ grams}}\right) \times \left(\frac{1 \text{ ton}}{2000 \text{ pounds}}\right)
\]

Aircraft model engine emission calculation spreadsheets are presented in Section 7.
4 UA Model Engine Emission Results

Table 4-1 shows the worst-case engine emissions in tons per year per hour (TPY/hour) for both the maximum and average hp of the model engines from Table 3-1, each pollutants’ de minimis threshold, and the hours per year needed to exceed the de minimis threshold for each pollutant. While there are no defined significance thresholds for aviation greenhouse gas (GHG) emissions, nor has FAA identified any factors to consider in making a significance determination for GHG emissions, GHG carbon dioxide (CO2) emissions are presented for informational purposes.

Using worst-case assumptions for engine hp and emission factors, Table 4-1 shows that the hours estimated to exceed the EPA de minimis thresholds are much higher than the total annual hours in a year (8,760 hours) for all criteria pollutants except the maximum hp engine case for Volatile Organic Compounds (VOCs). Even for VOCs, assuming the worst-case engine horsepower rating (22 hp) and worst-case VOC emission factor (51.406 g/hp-hour), the estimated hours to exceed the worst-case VOC threshold are 8,208 hours per year, which at 94 percent of the hours in a year is highly unlikely to ever be reached in practice.

5 Summary of Results

Air quality emissions from various types of UA engines were estimated to evaluate potential air quality impacts from the Proposed Action. For this analysis, the potential of exceeding the EPA NAAQS was assessed by estimating UA aircraft engine emissions using conservative (e.g., longer duration and higher throttle) assumptions and comparing them to worst-case EPA de minimis thresholds for significance. The analysis evaluated various commonly used aircraft engine types and estimated the number of hours of operation it would take to exceed the worst-case de minimis thresholds. In lieu of specific aircraft model engine emission factors, the EPA MOVES nonroad model was used to assign similar engine types within its database to the various common model aircraft engine types to generate emission factors for NAAQS criteria pollutants, assuming gasoline usage for fuel and a 2022 MOVES existing emission year. In addition, the MOVES representative equipment for each model engine type used to develop the emission factors incorporated county-level data representative of Palm Beach County, Florida for both criteria pollutants/precursors and GHGs. Palm Beach County was chosen since it is home to the largest UA club that operates out of West Delray Regional Park. The hours of operation per year needed for a worst-case hypothetical engine to exceed de minimis thresholds was determined. The worst-case de minimis thresholds (the lowest de minimis thresholds by pollutant based on attainment designation), represent emission quantities of a NAAQS-regulated pollutant, or its applicable precursors, over which a Proposed Action in an EPA-designated nonattainment or maintenance area may cause or contribute to a new or continued violation of the NAAQS. Annual emissions below the de minimis are considered not significant and are presumed to not exceed the NAAQS.

The results show that exceeding the de minimis thresholds for nearly all pollutants, assuming worst-case engine ratings and emission factors, would require total annual engine operating hours greater than the 8,760 total hours in a year for all pollutants, except the maximum engine hp case for VOCs. Even for the maximum hp engine case for VOCs, the estimated hours to exceed the worst-case VOC threshold are 8,208 hours per year, which is highly unlikely to occur in real-world circumstances.
6 Conclusions

6.1 Existing Flying Locations

For FRIAs designated at an existing flying site, the FAA anticipates there would be no change in existing conditions due to the generally enabled activities permitted by 14 CFR parts 107 and the location-specific limitations on UA operations and UA operators in part 89. Furthermore, it is expected that most recreational operators of UA would bring their non-compliant aircraft into compliance either by the Remote ID deadline or sometime after. Potential decreases in flight activity, assuming non-compliant operators cease flying, following the September 2023 compliance deadline would be temporary and negligible. As such, neither the Proposed Action nor the No Action Alternative would result in substantive changes to activity levels and their associated pollutant emissions at existing flying locations. Emissions from operations at FRIAs established at existing locations would not cause significant impacts to air quality, and it is improbable for UA operations to contribute to an exceedance of any regulatory standard.

6.2 New Flying Locations

For FRIAs designated at newly established flying locations, the FAA anticipates a de minimis change in existing conditions due to the presence of generally enabled activities permitted by 14 CFR parts 107 and the minor changes expected in UA operators’ behavior due to location-specific limitations on UA operations and UA operators in part 89. A temporary concentration of activity may occur at new locations that previously did not experience multiple operators within a confined area; however, the cumulative nature of these operations would still not trigger anything other than a negligible change in pollutant emissions. As such, neither the Proposed Action nor the No Action Alternative would result in substantive changes to activity levels and their associated pollutant emissions at existing flying locations. Emissions from operations at newly established FRIA locations would not cause significant impacts to air quality, and it is improbable for sUAS operations to contribute to an exceedance of any regulatory standard.

In summary, since the emissions individually and collectively are below the worst-case de minimis thresholds (or in the case of VOCs are expected to be in a real-world application), it can be concluded that the operation of UA would “not cause a significant air quality impact, since it is unlikely the pollutant emissions analyzed would exceed a NAAQS.” This conclusion applies to both existing and new flying locations, and at existing and reasonably foreseeable activity levels.

1 Introduction and Background

The Federal Aviation Administration (FAA) is implementing subpart C, FAA-Recognized Identification Areas (FRIA), of Title 14 of the Code of Federal Regulations (CFR) Part 89, Remote Identification of Unmanned Aircraft (Remote ID Rule) 86 FR 4390 (Jan. 15, 2021). Subpart C established a path through which eligible entities may seek approval from the FAA to establish a FRIA. After the Remote ID Rule is fully effective, unmanned aircraft (UA) equipped with remote identification technology can continue to operate nationally under existing regulations. All UA pilots required to register their aircraft must operate in accordance with the Remote ID Rule beginning September 16, 2023. The Remote ID Rule requires UA to be equipped with remote identification at locations outside of FRIA locations.

The FAA is evaluating whether the implementation of FRIAs could result in unmanned aircraft (UA) noise at or above the Day-Night Average Sound Level (DNL) 65 dB threshold for noise compatible land use. This document presents an analytical approach, and the associated results, for determining the numbers of flight events and time required for various types of UA operations to generate noise levels at or above DNL 65 dB.

The methodology proposed in this document provides quantitative guidance to the FAA in order to inform environmental decision making on UA noise exposure from the Proposed Action. The methods presented here are suitable for review of FAA actions under the requirements of the National Environmental Policy Act (NEPA) and other applicable environmental special purpose laws or other federal environmental review requirements at the discretion and approval of the FAA. In particular, this report is a nonstandard equivalent methodology under FAA Order 1050.1F, and as such, received written approval from the FAA’s Office of Environment and Energy (AEE).  

Section 2 of this document describes two sets of noise measurements that form the basis of the noise assessment presented herein. Section 3 describes the data collected during those noise measurements. Section 4 presents the analysis methodology applied to the noise measurement data. Section 5 presents the estimated activity level that would be required to generate DNL 65 dB for various types of UA.

---

1 Discussion of the use of “another equivalent methodology” is discussed in FAA Order 1050.1F, July 16, 2015, Appendix B, Section B-1.2, available online at https://www.faa.gov/documentLibrary/media/Order/FAA_Order_1050_1F.pdf#page=113
2 Unmanned Aircraft Noise Measurement Descriptions

Two data sets form the basis for the noise assessment presented in this document. The primary data set consists of fixed-wing UA noise measurement data collected by the FAA at the Prince Georges County Radio Controlled (PGRC) Club\(^2\) flying location in Upper Marlboro, MD on April 25, 2022\(^3\). The second data set consists of multicopter UA noise data collected by the U.S. Department of Transportation (USDOT) Volpe National Transportation System Center (Volpe) on July 15\(^{th}\) and July 16\(^{th}\), 2019\(^4\) at the Choctaw Nation of Oklahoma (CNO) Integrated Pilot Program (IPP) test site in Daisy, Oklahoma.

2.1 PGRC Club Noise Measurements

The PGRC measurement effort was coordinated with local members of Academy of Model Aeronautics (AMA) to capture noise from as many different UA types as possible in a single day. Various UA types were flown over a six-hour period, allowing for measurement of multiple flights from each aircraft type over the course of the day. The FAA categorized the UA measured according to general aircraft type and/or the engine used. All measured UA were fixed-wing aircraft. No helicopter or multicopter type UA were present for measurement. The categories of UA measured are presented in Table 1. For most UA categories, multiple UA (of the same category) were flown and captured in the noise measurements.

The PGRC Club noise measurements setup consisted of five total microphones placed at various locations around the facility property. Figure 1 presents an aerial view of the site with the locations of the five microphones labeled as M1 through M5 and an oval indicating the area in which most flight activity generally occurs. Three tripod mounted microphones (M1, M2, M3) were placed within the designated flight area, one tripod mounted microphone (M4) was placed in the parking lot at the edge

\(^2\)https://pgrcclub.com/
\(^3\)Power Point presentation and noise measurement data files provided to HMMH by FAA on July 26, 2022
of the facility property, and a spare microphone (M5) was placed on the ground adjacent to the facility runway. Due to its placement, microphone M5 data is not representative of noise levels that could be experienced by non-participants and as such the data is omitted from this report.

Figure 1. PGRC Club Noise Measurement Test Setup
Source: FAA, 2022

2.2 IPP CNO Volpe Noise Measurements

The IPP CNO noise measurement report (see footnote 4) is used as the source for multicopter noise data in this analysis, as no multicopters were operated during the noise measurements at the PGRC Club. The IPP CNO noise measurements captured data on four UA: three multicopters (DJI M200, Yuneec Typhoon, and Gryphon Dynamics GD28X) ranging from 5 to 45 pounds and a fixed-wing vehicle (Skywalker X-8) with a wingspan of about 7 feet. Measurements were conducted in a manner consistent with the existing noise certification requirements for light helicopters and small propeller-driven airplanes. Measurements were also taken with the vehicles operating on simulated missions unique to UA capabilities. Measured multicopter flight procedures covered vertical takeoff and landing operations, fast and slow (i.e., minimum and maximum engine power) level flyovers, and infrastructure inspection operations.

The IPP CNO measurement setup consisted of a total of three microphones placed under and adjacent to the UA flight path. Two microphones were placed on the center line directly under the flight path, an inverted ground plane microphone and a 4-foot-high pole-mounted microphone. An additional ground-
Unmanned Aircraft Noise Measurement Descriptions
Noise Assessment of Unmanned Aircraft
in Support of the FRIA Programmatic Environmental Assessment

Plane microphone was placed 20 feet west of the primary (center line) ground-plane microphone. Figure 2 presents an aerial view of the site with the locations of the three microphones labeled.

Figure 2. IPP CNPO Volpe Noise Measurement Test Setup
Source: Volpe, 2020

This document focusses solely on the noise data for the 45-pound GD28X. The GD28X, shown in Figure 3, was the heaviest UA measured at the CNO IPP site. The GD28X is an electrically powered octocopter (eight rotors) which can be flown at a maximum takeoff weight of 70 pounds, but for this test was limited to 45 pounds to comply with the FAA's Part 107 rule. The GD28X is over 4-and-a-half feet from rotor tip to rotor tip. Being the largest and noisiest of the three measured multicopters, the GD28X data provides a conservatively high representation of potential noise exposure for the multicopter category of UA.

Figure 3. Gryphon Dynamics GD28X

This page intentionally left blank.
3 Noise Measurement Data

This section presents the resulting data for the PGRC Club and IPP CNO Volpe noise measurements. It should be noted that the two measurements were conducted for different purposes under different conditions. As such, the data available from each differs in terms of the manner of quantifying UA flight noise.

3.1 PGRC Club Noise Measurement Data

For the PGRC Club measurements, UA were operated in a manner consistent with typical recreational flying, wherein the positions of the aircraft during the measurement were unprescribed and generally random.

Table 2 presents the measured DNL for each aircraft category as well as the total DNL of all flight activity during the 6-hour measurement period. The location of microphone M2 was nearest to the general flight area, receiving the most direct overflights, and consequently measured the highest overall DNL and typically the highest DNL for each category.

Because microphone M2 was within the general flight area and experienced the most direct UA overflights, its data was selected for use in further analysis to assess potential UA noise exposure related to flight operations within FRIAs. Table 3 presents additional details on the noise data collected at M2. Thirty-eight individual UA flights were measured at M2 with the average duration of flights ranging from approximately five to ten minutes. The electric sport and aerobat UA produced the lowest and highest noise levels, respectively. The average A-weighted maximum sound level ($L_{A_{max}}$) ranged from 59.1 to 85.3 dBA and the average A-weighted Sound Exposure Level ($L_{AE}$) ranged from 71.8 to 99.1 dBA.

3.2 IPP CNO Volpe Noise Measurement Data

For the IPP CNO Volpe measurements, the test was designed to capture UA noise for individual types of UA operations (e.g., takeoff, landing, level overflight) wherein the position of each aircraft during the measurement was prescriptive. Each operation type was repeated multiple times with the UA flown in a consistent manner for each pass by the microphones. This document uses data from the centerline 4-foot pole-mounted microphone, as its mounting is the most representative of what a listener would experience during UA overflights. Table 4 presents the average $L_{A\text{max}}$ and $L_{AE}$ as well as associated number of passes and average durations for flyovers and vertical takeoffs and landings. Table 4 also presents the average A-weighted Equivalent Continuous Sound Level ($L_{AEQ}$) for a 30-second hover.

Notes:
- Except for hovers, all data presented is for the centerline 4-foot pole (CLP) microphone. Hover data is from the Sideline Ground microphone.
- Hover measurements consisted of 30-second hovers with the UA pointed toward each cardinal direction.
- Data elements which are not applicable to particular operation types are denoted by "-".

Of the individual GD28X operation types measured, the $L_{A\text{max}}$ ranged from 66.1 to 73.2 dB and the $L_{AE}$ ranged 75.6 to 86.7 dB. Noise levels for vertical takeoff plus vertical landing are calculated by the decibel addition of the individual takeoff and landing noise levels. Static hovers were measured with the vehicle at 4 feet above ground level directed toward each of the four cardinal directions for 30-second intervals.
The Volpe report states that Centerline Pole microphone data for the GD28X was not collected during hover due to issues with measurement hardware. Due to this data being unavailable, Sideline Ground microphone data is presented in Table 4 and used in subsequent analysis (instead of Centerline Pole data). The average $L_{Aeq}$ for the four cardinal direction 30-second hovers was 76.4 dB.
4 Methodology for Data Analysis

The determination of activity thresholds for UA operations that would generate noise levels at or above DNL 65 dB is calculated by different methods, depending on whether the measured event is quantified in terms of $L_{AE}$ or $L_{Aeq}$. Only static hover events are quantified in terms of $L_{Aeq}$. All other measured dynamic events utilized in this analysis are quantified in terms of $L_{AE}$. In all instances, the results in Section 5 are presented in terms of Average Annual Day (AAD) DNL effective daytime values for events or flight time. Effective daytime numbers of events or flight time is defined as follows in Equation 1.

$$N_{d eff} = N_d + \left( 10 \times N_n \right)$$  \(1\)

Where:
- $N_d$ = flight events or hover hours occurring during the daytime from 7:00 a.m. to 9:59 p.m.
- $N_n$ = flight events or hover hours occurring during the nighttime from 10:00 p.m. to 6:59 a.m.

Equation 1 may be rearranged to calculate an equivalent result for all activity occurring during the nighttime period, i.e., where $N_d = 0$, as follows in Equation 1.1.

$$N_n = \frac{N_{d eff}}{10} \quad \text{(1.1)}$$

As such, the results in Section 5 may be converted to all nighttime activity equivalent values by dividing the presented value by 10.

Section 4.1 contains the $L_{AE}$ methodology, Section 4.2 contains the $L_{Aeq}$ methodology, Section 4.3 contains an aggregate methodology for determining $N_{d eff}$ for combined static and dynamic events, and Section 4.4 discusses the determination of the flight times associated with the resulting $N_{d eff}$.

4.1 Sound Exposure Level Methodology

Numbers of effective daytime flight events required to generate DNL 65 dB are calculated from the measured $L_{AE}$ as follows in Equation 2.

$$\text{Flight Events } N_{d eff} = \frac{\left( \frac{65}{10} \right)}{10^{-\left( \frac{L_{AE} - 49.4}{10} \right)}}$$  \(2\)

4.2 Equivalent Continuous Sound Level Methodology

For vehicles hovering in place, the number of effective daytime hover hours required to generate DNL 65 dB are calculated from the measured $L_{Aeq}$ as follows in Equation 3.
4.3 Aggregate Methodology

Static hover noise is combined with dynamic flight event noise utilizing a three-step process to determine $N_{d\ eff}$ flight events for the aggregate. In Step 1, the static hover $L_{Aeq}$ for some fixed period of time in seconds, denoted as $t$, is converted to an equivalent $L_{AE}$ as follows in Equation 4.

$$Hover\ L_{AE} = L_{Aeq} + 10 \log_{10} t$$

In Step 2, the $L_{AE}$ values for the static and dynamic events are added together by standard decibel addition as follows in Equation 5.

$$Combined\ L_{AE} = 10 \log_{10} \left[ \sum_{i}^{n} \frac{L_{AE}}{10} \right]$$

The third and final step uses the output of Equation 5 as the input to Equation 2 to calculate the resultant $N_{d\ eff}$ for aggregate flight events to generate DNL 65 dB.

4.4 Flight Hours

Flight hours associated with the $N_{d\ eff}$ flight events to generate DNL 65 dB are also calculated. Associated flight hours are determined by multiplying the resulting $N_{d\ eff}$ by the average UA flight and event type durations presented in Table 4 and Table 5.
5 Noise Exposure Estimate Results

By application of the equations presented in Section 4 to the measurement data presented in Section 3, effective daytime Annual Average Daily (AAD) flight events and hours were calculated for DNL 65 dB.

5.1 PGRC Club Noise Assessment Results

For the fixed-wing UA measured at the PGRC Club, AAD $N_{d\text{ eff}}$ flights ranged from approximately 33 to 18,000 per day, equating to a range of AAD $N_{d\text{ eff}}$ flight hours between approximately 6 to 2,086 per day. Only 3 of the measured aircraft categories were calculated to produce DNL 65 dB in less than 24 hours of average daily flight time, the Aerobat at 5.7 hours, Big Engine at 13.3 hours, and Twin Engine at 21.6 hours. The three noisiest aircraft were all 2-stroke gas engine propeller driven planes that were the largest of the UA present for PGRC Club measurements. Figure 4 and Figure 5 present the results for the fixed-wing UA measured at the PGRC Club.

![Figure 4. Fixed-wing UA AAD $N_{d\text{ eff}}$ Flight Events for DNL 65 dB at Microphone M2](Source: HMMH)
5.2 IPP CNO Noise Assessment Results

For the GD28X multicopter UA measured at the CNO IPP site, AAD $N_{d, eff}$ flights ranged from approximately 80 to 7,500 per day, equating to a range of AAD $N_{d, eff}$ flight hours between approximately 4 to 88 per day. These ranges include event type sequences, like vertical landing plus hover plus vertical takeoff, that were not directly measured but estimated by combing the measured noise levels and associated durations of the individual component operations to approximate a broader range of potential flight activity. It should be noted that the UA when in hover and during vertical takeoff and landing is within approximately 30 feet of the microphone, making the results presented here representative of what would typically only be experienced by someone participating in the operation of the UA. Figure 6 and Figure 7 present the results for the GD28X multicopter UA measured at the IPP CNO site.
Figure 7. GD28X Multicopter AAD $N_{d_{eff}}$ Flight Hours for DNL 65 dB

Source: HMMH
This page intentionally left blank.
## 6 Conclusion

The number of flight events and associated flight time required for UA to generate noise levels at or above DNL 65 dB was estimated using available noise measurement data for small (i.e., under 55 pounds) fixed-wing and multicopter UA. The results of the analysis show that, for the measured UA, the number of AAD flight events and associated flight times required to produce DNL 65 dB at a fixed receiver location within a flight area is generally much higher than what would be likely or practically possible to occur in foreseeable real-world conditions.

### 6.1 Applicability of Noise Analysis Results to Potential UA Activity

As stated previously, FAA anticipates UA operations within FRIAs could include fixed-wing, helicopters, and multicopters equipped with an electric motor, gas engine, or turbine engine. As such, the noise data used for this analysis does not cover all UA types that could potentially operate within a FRIA. Table 5 presents an inventory of the UA types used for this analysis in the context of all potential UA types. The noise measurement data used for this analysis covers all engine types for fixed-wing UA and multicopter UA with electric engines. However, it does not include multicopter UA with gas or turbine engines, or any type of helicopter UA.

</tbody>
</table>

Current multicopter UA primarily use electric engines and that is expected to remain true for the foreseeable future. While it is recognized that multicopter UA with gas or turbine engines could operate within FRIAs, the existence and operation of such UA is expected to be rare. Helicopter UA with all three engine types are currently operated by hobbyists and can be expected to operate within FRIAs, though...
likely at lower activity levels than fixed-wing UA as they tend to be less common. While this analysis did not have available helicopter UA noise data for estimating threshold levels of flight activity to produce DNL 65 dB, the resulting ranges for the available data are likely to be representative of similarly sized helicopter UA given the representative spread of engine types and sizes present in the fixed-wing data and similarity/overlap of engines used across hobbyist UA.

Collection of additional noise data and further noise analysis may be warranted to evaluate the potential for noise exposure impacts at flying locations expected to have a substantial portion of flight activity from helicopter UA and/or multicopters with gas or turbine engines, and for flying locations expected to have frequent activity by any UA heavier than 55 pounds. However, significant noise impacts are unlikely to result in any case given that the FAA anticipates that the implementation of the Remote ID rule, and FRIAs to accommodate operation of UA without remote ID, to have a very little effect on the overall level of activity occurring at existing or new flying locations.

6.2 Existing Flying Locations

For FRIAs designated at an existing flying location, the FAA anticipates there would be no change in existing conditions due to the general ability to fly UA for recreation under 49 U.S.C § 44809. Furthermore, it is expected that most recreational operators of UA would bring their non-compliant aircraft into compliance either by the Remote ID deadline or sometime after. Potential decreases in flight activity, assuming non-compliant operators cease flying, following the September 2023 compliance deadline would be temporary and negligible. As such, neither the Proposed Action nor the No Action Alternative would result in substantive changes to activity levels and their associated noise exposure at existing flying locations.

6.3 New Flying Locations

For FRIAs designated at newly established flying locations, the FAA anticipates flight activity increases relative to existing conditions to be minor due to the presence of general ability to fly UA for recreation under 49 U.S.C § 44809. Resulting concentrations of activity occurring at new locations that previously did not experience multiple operators within a confined area would be temporary. As such, neither the Proposed Action nor the No Action Alternative would result in substantive changes to activity levels and their associated noise exposure at new flying locations.
Appendix C

Non-Standard Noise Methodology Memos
FAA Flight Standards Service (AFS) requests FAA Office of Environmental and Energy (AEE) Noise Division (AEE-100) approval of the noise methodology to be used for the Programmatic Environmental Assessment (PEA) for FAA-Recognized Identification Areas (FRIAs) under the Remote Identification of Unmanned Aircraft Final Rule (14 CFR Part 89), as described below.

As required under the National Environmental Policy Act (NEPA), the FAA must consider the potential for environmental impacts in informing the agency's decision to approve Federal actions, including the potential for noise impacts as detailed in FAA Order 1050.1F.

As the FAA does not currently have a standard approved noise model for UA, this memo serves as a request for written approval from AEE-100 to use the methodology proposed in the following sections to support the noise analysis for this PEA.

Description of Aircraft and Proposed Operations

AFS is evaluating whether the implementation of FRIA approvals could result in unmanned aircraft (UA) noise at or above the thresholds of Day-Night Average Sound Level (DNL) 65 dB or an increase of 1.5 dB or greater within DNL 65 dB for noise compatible land use. A FRIA is a defined geographic area where unmanned aircraft can be flown without remote identification equipment. Both the UA and the pilot must be located within the FRIA's boundaries throughout the operation. In addition, the pilot of the unmanned aircraft must be able to see it at all times throughout the duration of the flight. Only FAA-recognized Community Based Organizations and educational institutions such as primary and secondary schools, trade schools, colleges, and universities are eligible to request the establishment of a FRIA. If the FAA approves the establishment of a FRIA, the approval will be valid for 48 calendar months.
To establish a FRIA, eligible entities must submit applications to the FAA for proposed locations. FAA approval of a FRIA only relates to its location, it does not approve construction or other infrastructure development. Following establishment, UA may be operated within FRIA boundaries without Remote ID technology as long as the UA remains within the operator's visual line of sight and neither the operator nor the UA travel beyond the boundaries. The UA operated at FRIAs may include fixed-wing, helicopters, and multicopters equipped with an electric motor, gas engine, or turbine engine.

The primary data set in the noise assessment consists of fixed-wing UA noise measurement data collected by the FAA at the Prince Georges County Radio Controlled (PGRC) Club flying location in Upper Marlboro, MD. The PGRC measurement effort was coordinated with local members of Academy of Model Aeronautics (AMA) to capture noise from as many different UA types as possible in a single day. Various UA types were flown over a six-hour period, allowing for measurement of multiple flights from each aircraft type over the course of the day consistent with typical operations of the UA. The FAA categorized the UA measured according to general aircraft type and/or the engine used and are summarized in Table 1 below. All measured UA were fixed-wing aircraft.

The secondary data set in the noise assessment consists of multicopter UA noise data collected by the U.S. Department of Transportation (USDOT) Volpe National Transportation System Center (Volpe) at the Choctaw Nation of Oklahoma (CNO) Integrated Pilot Program (IPP) test site in Daisy, Oklahoma. The IPP CNO noise measurement report was used as the source for multicopter noise data in the noise analysis, as no multicopters were operated during the noise measurements at the PGRC Club. The IPP CNO noise measurements captured data on four UA: three multicopters (DJI M200, Yuneec Typhoon, and Gryphon Dynamics GD28X) ranging from 5 to 45 pounds and a fixed-wing vehicle (Skywalker X-8) with a wingspan of about 7 feet. Measurements were conducted in a manner consistent with the existing noise certification requirements for light helicopters and small propeller-driven airplanes. Measurements were also taken with the vehicles operating on simulated missions unique to UA capabilities. Measured multicopter flight procedures covered vertical takeoff and landing operations, fast and slow (i.e., minimum and maximum engine power) level flyovers, and infrastructure inspection operations.

The FAA expects UA operations at proposed FRIA flying locations would typically involve one UA in the air at a time, with operations lasting a few hours per day up to seven days per week. The numbers of flight events and associated flight time required for UA to generate noise levels at or above DNL 65 dB was estimated using available noise measurement data for small (i.e., under 55 pounds) fixed-wing and multicopter UA.

**Noise Analysis Methodology**
The Office of Environment and Energy (AEE) has reviewed the proposed non-standard noise modeling methodology to be used for FAA-Recognized Identification Areas (FRIAs) under the Remote Identification of Unmanned Aircraft Final Rule. This request is in support of a Programmatic Environmental Assessment (PEA) for the nationwide establishment of FRIAs.

The Proposed Action is to allow eligible entities such as primary and secondary schools, trade schools, colleges, and universities to submit applications to the FAA to allow for the establishment of FRIAs. A FRIA is a defined geographic area where UA can be flown without remote identification equipment. Once an application for establishment of a FRIA is approved by the FAA, eligible entities can fly UA without remote identification equipment provided the UA remains within the operator's visual line of sight and neither the operator nor the UA travel beyond the established FRIA boundaries. The UA operated at FRIAs may include fixed-wing, helicopters, and multicopters equipped with an electric motor, gas engine, or turbine engine. The FAA expects UA operations at proposed FRIA locations would typically involve one UA in the air at a time, with operations lasting a few hours per day up to seven days per week.

To evaluate the noise levels from the Proposed Action, the numbers of flight events and associated flight time required for UA to generate noise levels at or above DNL 65 dB was estimated using available noise measurement data for fixed-wing and multicopter UA. Noise measurement data for the noise analysis was based on two data sources. Fixed-wing UA noise measurements were based on measurements collected by the FAA at the Prince Georges County Radio Controlled (PGRC) Club in Upper Marlboro, MD, and multicopter UA noise measurements were collected by the U.S. Department of Transportation (USDOT) Volpe National Transportation System Center (Volpe) at the Choctaw Nation of Oklahoma (CNO) Integrated Pilot Program (IPP) test site in Daisy, Oklahoma, respectively.
As the FAA does not currently have a standard approved noise model for assessing UA, and in accordance with FAA Order 1050.IF, all non-standard noise analysis in support of the noise impact analysis for the National Environmental Policy Act (NEPA) must be approved by AEE. This letter serves as AEE's response to the method developed in HMMH Report No. 313090.002 001-lg for "Noise Assessment of Unmanned Aircraft In support of the FAA-Recognized Identification Areas Programmatic Environmental Assessment" dated March 23, 2023.

The proposed methodology appears to be adequate for this analysis; therefore, AEE concurs with the methodology proposed for this project. Please understand that this approval is limited to this particular Environmental Review for the establishment of FRIAs. Any additional projects using this or other methodologies will require separate approval.
Appendix D

Public Comments and FAA Responses
Appendix D: Public Comments and FAA Responses

Dave Messina, President and CEO, FPV Freedom Coalition, Malden on Hudson, New York, 12453

May 2, 2023

The FPVFC disagrees with the following assumptions in the document:

Comment #1:

Overall document. The PEA FRIA includes many references to the AMA. The document incorrectly references the AMA as representing 95% of the recreational sUAS population. We strongly disagree with this assumption. Using the FAA’s own projections, there are approximately 1.78 million sUAS recreational flyers in the USA as of today, May 2023. An estimate of the AMA’s paying membership is approximately 100,000. That means the AMA represents closer to 5% of the sUAS flyer population and nowhere near the 95% cited in the PEA FRIA. The other 1.68 million sUAS recreational flyers are represented by the other three FAA recognized Community Based Organizations including Flite Test Community Association, STEM+C and the FPV Freedom Coalition. No effort was made to contact any of the other three CBO’s who represent 95% of the recreational population. As detailed below, we assert the requirements of the AMA do not represent the 95% of the remaining recreational population as the remaining 95% represents a more economically diverse and younger population including underprivileged individuals.

FAA Response to Comment #1:

The FAA did not intend to reference AMA as representing 95 percent of the recreational UA population. Rather, the FAA estimated that AMA flying locations comprise approximately 95 percent of known recreational flying club locations associated with CBOs in the U.S. This sentence in the PEA has been edited accordingly.

The FAA had no information about flying locations associated with the Flite Test Community Association, STEM+C, or FPVFC when preparing the Regulatory Impact Analysis (RIA) for the Remote ID Rule.44 These non-AMA CBOs did not have established flying club information that was available to the FAA. However, based upon the applications received to date, the FAA believes that the assumptions and projections in the RIA and the PEA remain accurate.

Additionally, the commenter’s assertion that these other three CBOs represent 95 percent of the recreational UA community is inaccurate. While non-AMA recreational UA flyers may be required to operate in accordance with the safety guidelines of one of the other CBOs, it does not always mean that they are represented by that CBO.

The PEA incorporates data and assumptions made by the FAA in the RIA for the Remote ID Rule, which was prepared in accordance with the requirements and direction set forth in Executive Order (EO) 12866, Regulatory Planning and Review,45 and U.S. Office of Management and Budget (OMB) Circular A-4, Regulatory Analysis.46

---

Consistent with FAA practice when completing RIAs for UAS rulemakings, the FAA used a five-year time horizon in the Remote ID RIA to assess the cost-benefits of the Remote ID Rule as that aligns with historical and current FAA UAS Forecasts. The RIA relied on the FAA’s fleet forecast for small unmanned aircraft as published in the FAA Aerospace Forecast 2020-2040.47 (See NPRM pages 72489-72492 for more information.)

The FAA also incorporated into the PEA assumptions regarding the proliferation of UA-related programs that may request a FRIA in educational institutions and community-based organizations such as the AMA. As set forth in the RIA, the FAA assumes that all AMA flying sites will submit requests to establish FRITAs, and that 90 percent of these requests would be approved. The FAA estimated that approximately ten percent of flying sites associated with the AMA will be in sensitive areas and therefore will not be approved to establish a FRIA in publicly accessible locations.

Comment #2:

Section 1.1 Overview, 3rd paragraph, 7th sentence: “While the FAA expects the majority of requests to establish FRIA locations to correlate with existing locations of hobbyist clubs associated with the Academy of Model Aeronautics, and educational institutions such as JROTC schools, not all eligible entities48 are yet known to the FAA. Eligible entities may include organizations who do not currently operate UA at a specific location, but which may be formed in the future and would also be eligible to establish FRITAs.”

The FPVFC asserts this assumption is invalid because the AMA represents approximately 1/20th or approximately 5% of the sUAS operators in the USA and the FRIA program should not serve only a privileged minority. As referenced in section 3.2 No Action Alternative, in this document, the FAA’s 2020 estimates are 1.32 million recreational UA by the end of 2019 and using that reports growth rate, there are 1.78 million sUAS recreational operators exist in the USA as of today, May 2023. The FRIA program would be terribly insufficient, non-inclusive and discriminatory if it served only 5% of a population.

FAA Response to Comment #2:

The FAA acknowledges that AMA represents approximately five percent of UA operators in the U.S. Additionally, the FAA recognizes that other CBOs will seek to establish FRITAs at some of their respective flying locations. However, it is not correct that that all UA operators will need to operate only within FRITAs to remain compliant with the Remote ID Rule, as FRITAs are not the only way for a recreational flyer to comply with Part 89; compliance may also be achieved through the use of a standard Remote ID UA or a UA with a Remote ID broadcast module. As referenced on page 29-32 of the RIA, the FAA estimates the average lifespan of a sUAS is three years, so the vast majority of UAs will comply with part 89 requirements by the operational compliance date.

Comment #3:

48 Eligible entities include FAA-recognized community-based organizations and educational institutions including primary and secondary educational institutions, Junior Reserve Officers’ Training Corps (JROTC) programs, trade schools, colleges, and universities. 14 CFR 89.205.
Section 1.2 Background, paragraph # 5, the FAA states: “The FAA expects that the vast majority of UA will comply with remote identification requirements, thereby limiting the need for FRIAs. However, the FAA estimates that it may receive more than 4,000 FRIA applications by the full Remote ID Rule compliance date of September 16, 2023.”

a. The assumption that most of the 1.78 million sUAS operators will comply with remote identification requirements has no basis in fact. The remote ID NPRM prompted a record 53,000 comments. There is a widespread view, communicated in many of the 53,000 comments, that remote ID has no bearing on safety. The FAA has denied numerous FOIAs to produce a risk assessment of remote ID. Further, the FAA’s initial estimates that a remote ID broadcast module would cost between $30 and $50 are proving low by an order of magnitude. The cost to operators without any safety benefit to operators or crewed aircraft shows remote ID as a rule which is widely viewed as over-reach and unreasonable. As in the past, unreasonable regulations are met with widespread non-compliance. FPVFC anticipates wide-spread non-compliance with remote ID and therefore the need for FRIAs is amplified, not reduced. If the FAA were to consider twenty sUAS operators per FRIA, with a total of 1.78 million sUAS operators (the FAA’s estimate), that would result in a need for 89,000 FRIAs. The FPVC views the value of 4,000 as too small by a factor of 22.

FAA Response to Comment #3:
The FAA believes that the majority of operators will comply with Remote ID requirements. The FAA maintains a UA registration database and understands that many UA models will already be Remote ID-compliant by the implementation date, and other models can be retrofitted with a compliant Remote ID broadcast module. Additionally, the UAS Declaration of Compliance portal (https://uasdoc.faa.gov/listDocs) shows that there are already more than 100 FAA-accepted Declarations of Compliance for standard Remote ID-compliant UAs and Remote ID broadcast modules. Therefore, the FAA can confirm that most UA will likely comply with Remote ID requirements by the compliance date. The FAA made a minor edit to the sentence referenced by the commenter to clarify that most UA – instead of the vast majority of UA – will comply with Remote ID requirements and the operators of those aircraft will therefore have no need to seek out FRIA locations.

Comment #4:
Background 1.2, Existing Locations. The FAA states, “Similarly, the FAA anticipates that the VLOS boundaries of these locations, existing UA operations, UA types, and operating characteristics will remain static. Based on information provided by the AMA, the FAA estimates that approximately 2,500 existing locations associated with the AMA may request FRIAs between September 2022 and September 2023. In addition, the FAA estimates that an additional 100 locations at which UA operations currently take place but which are not associated with the AMA may also seek FRIA establishments during the same time period.”

b. This assumption defies logic. This paper identifies the FAA report which estimates Recreational sUAS operators in 2023 at 1.78 million. How could it be possible to serve 95% of this population with 100 FRIAs while 100% of the AMA’s existing 2,500 sites, serving 5% of the Recreational population? The FPVFC asserts this assumption is completely invalid and is exclusionary.
c. In a similar vein, in the next paragraph, the FAA states, “Based on the Regulatory Impact Analysis prepared by the FAA in conjunction with the Remote ID Rule, it is anticipated that, between September 2022 and September 2023, educational institutions may request to establish FRIAs at approximately 1,800 locations where UA are currently operated.” With 56 million students how is it possible to derive only 1,800 FRIAs from all the schools and educational institutions in the USA. The FPVC again asserts this assumption is low by two to three orders of magnitude. To be clear, we are stating this estimate is likely too low by a factor of over 100 to 1,000.

FAA Response to Comment #4:

The commenter’s assertion that most UA operators will need to operate only within FRIAs is incorrect. There are other ways to comply with Remote ID – besides operating only in a FRIA. The FAA maintains that most recreational UA operators will be compliant through a standard Remote ID UA or with a Remote ID broadcast module.

Additionally, the statements about the number of educational institutions that were projected to apply for a FRIA are incorrect. The FAA referenced FRIA projections from the RIA that was published in support of the Remote ID Rule, in which the FAA estimated that 1,700 Junior Reserve Officers’ Training Corp Units and 66 institutions identified as awarding undergraduate degrees in aerospace engineering will submit requests to establish FRIAs. The FAA had limited information on the number of K-12 schools that may seek to establish a FRIA, and therefore they were not included in the RIA.

The projections in the RIA were estimates and the actual numbers may be higher or lower; however, based on the number of FRIAs the FAA has already reviewed, the FAA has seen no indication that the actual number of approved FRIAs will be significantly higher or lower than the RIA estimates.

Comment #5:

Background, 1.2 New Locations. The assumptions in this paragraph are stated as, “Based on information provided by AMA, the FAA estimates that approximately 80-85 new locations may seek FRIAs annually between September 2022 and September 2027. The FAA also anticipates that non-AMA member organizations recognized by the FAA as a CBO may seek to establish approximately four new FRIAs annually between September 2022 and September 2027. As with existing educational locations, the FAA anticipates that these locations would be established on landscaped school-owned property and likely to be located on open lots. It is also possible that the locations may be established on property otherwise being used for aviation-related use or where UA currently operates in compliance with legal requirements. The FAA anticipates that educational institutions may establish as many as 625 new FRIAs between September 2022 and September 2027. This assumption is informed by changes in STEM curricula being offered in primary and secondary school.” The FPVFC asserts these estimates are also too low by a factor over 10,000. Our math is: There are 1.78 million sUAS operators, the FAA is instituting remote ID in September 2023. For these operators to fly legally, they would need to either purchase a remote identification at a price which could be double the price of their model aircraft or fly in a FRIA. Therefore, a FRIA would be very attractive. As we cited above, if we were to assume 20 sUAS operators per FRIA, that would mean 1.78 million divided by 20 or 89,000 FRIAs. How the AMA and FAA arrive at an estimate of 80 to 85 makes no sense. We could look at this from the population of students. From conservative estimates, if we consider maybe 1 student in a
thousand would be a recreational sUAS operator in an educational STEM program, that would be 56,000 students. If we use the same ratio of 20 sUAS operators per FRIA, that will yield a need for 2,800 FRIAs or only a factor of 35 times the FAA’s estimate of new FRIAs.

**FAA Response to Comment #5:**

Although the commenter asserts that there will be a need for all recreational UA operators to purchase a Remote ID-compliant UA or fly only in established FRIAs, the FAA understands that many UA models will already be compliant. Based on the information available to the FAA when preparing the RIA projections, the FAA anticipates that most FRIAs will be established at locations where UA operations are already occurring, and therefore would be considered as existing locations for analysis purposes under the FRIA PEA. The FAA maintains that its projections for new locations also are valid.

**Comment #6:**

Section 1.2, Background. Footnote #6, page 4. The footnote reads, “The FAA estimates that AMA members comprise approximately 95 percent of the recreational flyer community in the United States.” This footnote is incorrect. By the FAA’s own estimates, there are 1.78 million recreational sUAS flyers in the USA. The AMA has 100,000 paying members. That’s closer to 5.6% and nowhere near 95%. The magnitude of this error calls into question the validity of this entire PEA FRIA as the FAA has ignored the other 3 Community Based Organizations and discussed the PEA with only one CBO who represents just over 5% of the recreational population. Further, the demographic of the AMA is monolithic in that the overwhelming majority of its members are older men.

**FAA Response to Comment #6:**

As stated previously in the response to comment #1 in this commenter’s submittal, the FAA did not intend to reference AMA as representing 95 percent of the recreational UA population. Rather, the FAA estimated that AMA flying locations comprise approximately 95 percent of known recreational flying club locations associated with CBOs in the U.S. This sentence in the PEA has been edited accordingly.

**Comment #7:**

No Action Alternative 3.2. 2nd paragraph. The FAA states, “Following the FAA’s issuance of the Part 107 rule and amendments, the FAA’s 2020 forecasts determined that approximately 1.32 million UA distinctly identified as recreational aircraft were owned at the end of 2019, and estimated that ownership rates would continue to grow annually at approximately 6 percent per annum before plateauing at approximately 1.5 million UA as the pace of falling prices diminishes and early adopters of UA begin to experience limits in their experiments, or as eagerness plateaus.” The FPVFC sees no evidence that sUAS growth will plateau and therefore this assumption is invalid. Flite Test, a company headquartered in Malvern, Ohio has transformed the demographic of fixed wing recreational aircraft use and has over 2.1 million followers. Flite Test has created a community it reaches directly through social media. This community is diverse and spans income brackets and spans a broad age range.

**FAA Response to Comment #7:**

The FAA does not agree with the commenter’s statements about UA ownership numbers and expected growth rates. The RIA relied on the FAA’s fleet forecast for small unmanned aircraft as
published in the FAA Aerospace Forecast 2020-2040, which explained the key assumptions and data sources it relied upon to assess the rule’s impacts (see NPRM pages 72489-72492). The total number of Flite Test’s social media followers does not have any bearing on the FAA’s UA ownership projections.

Comment #8:

No Action Alternative 3.2. 3rd paragraph. The FAA states, “For example, UA operators have publicly stated that many models and types of UA can comply with the requirements of the Remote ID Rule via a software update or through the installation of an after-market broadcast module.” The FPVC strongly disagrees with this assertion. First, DJI, the largest manufacturer of video multirotors is abandoning most of its installed base of aircraft and not providing a software update to provide remote ID function. FPVFC anticipated this from DJI as DJI has a record of abandoning their installed base. In addition, the addition of a broadcast module is only applicable to aircraft manufactured prior to September 16, 2022, if the aircraft is to be used for part 107 operations and all recreational sUAS. The FPVFC therefore asserts these assumptions are incorrect. And the FAA’s assumption in the next sentence that it anticipates the “vast majority of the UA will comply with the Remote ID Rule” is not valid as it is based on assumptions which are incorrect.

FAA Response to Comment #8:

The commenter’s statements about DJI are noted. The UAS Declaration of Compliance portal (https://uasdoc.faa.gov/listDocs) shows that there are already more than 100 FAA-accepted Declarations of Compliance for standard Remote ID-compliant UAs and Remote ID broadcast modules. Through FAA-accepted Remote ID declarations of compliance already on the portal, the FAA is aware that many UA manufactured prior to the Remote ID production compliance date can comply with a standard remote ID UA through a software update. For UA unable to comply with a standard remote ID UA, an after-market remote ID broadcast module offers an alternative for compliance. The language regarding the “vast majority” has been edited to clarify that “most” UA will be able to comply with the Remote ID Rule and will therefore be able to operate outside of approved FRIA boundaries.

Comment #9:

Under the section for "Socioeconomic Impacts, Environmental Justice, and Children’s Environmental Health and Safety Risks" the FAA states, "The proposed action would not result in effects that would be predominately or uniquely borne by a minority or low-income population." However, one could argue that if the FAA does NOT approve FRIAs in specific areas, or significantly increase the number of expected FRIA locations, especially in low-income or urban areas, the FAA would be disproportionately inconveniencing people living there as most existing flying sites are quite far from these places and may be difficult to travel to.

FAA Response to Comment #9:

There is no basis for the assertion that the FAA would not be approving FRIAs within reasonable commuting distances from low-income or urban areas and that this would be disproportionately inconveniencing people living in those communities. As described in the PEA, FRIAs may be
requested by FAA-recognized CBOs and educational institutions whether they are in low-income communities or elsewhere. Additionally, the FAA reiterates that most UA operators will be able to comply with Remote ID without having the need to fly only within the boundaries of approved FRIA locations.

The FPVFC disagrees with the following conclusions or actions:

**Comment #10:**

Section 1.2 Background, paragraph #6, states, “This PEA does not include an analysis of temporary use events such as air shows or drone racing events as the FAA is not planning to approve FRIsA for temporary use events.”

a. The FPVFC asks the question: Why not? The FPVFC has been advocating the FAA to address temporary use events for over four years and the FAA’s response has been that it is working on it.

**FAA Response to Comment #10:**

The FAA’s decision to not include temporary events is because a FRIA, once approved, is valid for four years. As such, the regulatory framework of part 89 precludes the use of a FRIA for temporary events. Instead, the FAA can provide authorizations pursuant to 14 C.F.R. § 89.105 as necessary for temporary events, as appropriate.

**Comment #11:**

Section 4.4.3 Environmental Consequences, Proposed Action Alternative, 5th paragraph reads, “Therefore, because there is no change in the environmental baseline at existing flying sites, potential impacts from FRIA approvals on wildlife would not be significant. At new flying sites requesting a FRIA approval, the FAA will conduct further site-specific analysis to determine whether any wildlife or critical habitat could be affected.” This paragraph appears to contradict Table 4-1 on page 38 which indicates the FAA analysis finds approving FRIsA at UA flying locations would not cause:...

This may be the most significant area of concern by FPVFC. If we understand the statement from 4.4.3 quoted above correctly, this means that existing locations do not require an endangered species or other wildlife investigation as described in 4.4.3 but new locations requesting a FRIA do. If we understand the statement in 4.4.3 correctly, our judgement is this will dramatically reduce the total number of FRIAs and will raise the cost of applying for a FRIA beyond any organization we have encountered in over 50 years of flying RC model aircraft.

**FAA Response to Comment #11:**

Site-specific analyses for potential impacts to biological resources at new locations will not dramatically reduce the total number of FRIAs or raise the cost of applying for FRIAs. The FAA is responsible for completing further analyses at new FRIA locations, and this will not result in costs to FRIA applicants. The FAA edited the text of the Biological Resources section in Table 4-1 to clarify that the approval of FRIAs at existing locations would not cause significant impacts, and that new locations will require further analysis to confirm that there will be no significant impacts at those locations. No further analysis is conducted at existing locations seeking a FRIA because the FAA has determined that there will be no change in the environmental baseline at existing flying locations.
May 3, 2023

The Commercial Drone Alliance (“CDA”) welcomes the opportunity to comment on the Federal Aviation Administration’s (“FAA”) Programmatic Environmental Assessment (“PEA”) for FAA-Recognized Identification Areas (“FRIAs”).

The CDA is an independent non-profit organization led by key members of the commercial drone industry. The CDA brings together commercial drone end-users; manufacturers; service providers; advanced air mobility companies; drone security companies; and vertical markets including oil and gas, precision agriculture, construction, security, communications technology, infrastructure, newsgathering, filmmaking, and more. The CDA works with policymakers across government to craft policies for industry growth and seeks to educate the public on the safe, responsible use of commercial drones to achieve economic benefits and humanitarian gains.

The CDA supports the FAA’s efforts to proceed with the approval and establishment of FRIAs as provided for in 14 C.F.R. Part 89. The FAA’s 2021 Remote ID Rule defined a FRIA as a geographic area where uncrewed aircraft can be flown without remote identification equipment. FAA-recognized Community Based Organizations and educational institutions such as primary and secondary schools, trade schools, colleges, and universities are eligible to request the establishment of a FRIA. The availability of FRIAs will help move research, learning, and operations about uncrewed aircraft systems (“UAS” or “drones”) forward, given that FRIAs encourage participation in aviation for educational purposes. In addition to recreation and education, FRIAs may be used to support workforce development training. The FAA has prepared this PEA to evaluate the potential environmental impacts associated with the determination of whether to approve or deny applications to establish FRIAs.

The CDA recognizes that environmental review is a critical piece of the regulatory framework for enabling UAS operations to scale in the U.S. With this PEA to evaluate the potential environmental impacts associated with establishment of FRIAs, the FAA has appropriately applied a programmatic approach to the environmental review of UAS flight operations which are similar in nature and environmental impacts. Consistent with the Council on Environmental Quality regulations and guidance, and as demonstrated in the draft PEA, the use of a programmatic approach for this evaluation is an effective and efficient approach to environmental analysis of similar types of drone operations across the country. Significantly, the framework established in the PEA will allow for tiering, where appropriate, so that any proposed project, operation, or other action that may have unique specific environmental impacts requiring additional analysis may be studied to supplement the analysis set forth in the PEA. In such cases where an individual FRIA location may warrant additional environmental analysis and documentation, the environmental review will focus only on the specific issue at that particular FRIA that falls outside the review of this PEA.

By allowing for tiering, the efficiencies and effectiveness of this approach are substantial. The ability to tier off a PEA with a separate environmental review is an effective means of ensuring that any proposed project, operation, or other action that may have specific impacts is studied further.
As UAS technology continues to evolve (including with respect to noise level reduction) and commercial drone use expands in the United States, the use of programmatic environmental analysis approaches will support the successful deployment of these technologies and the realization of the countless public benefits of UAS operations for Americans, American businesses, and American communities. Notably, societal benefits include significant environmental benefits. For example, a wide variety of industries are counting on UAS to help decarbonize their operations, particularly those that currently rely on larger, louder gas-powered vehicles. Existing commercial drone deployments have already demonstrated a net positive impact on the environment—including reductions in overall noise levels and CO2 greenhouse gas emissions. Two 2021 studies found that drone-based delivery reduced delivery carbon emissions and energy usage by 96-98% compared to cars, a significantly larger reduction than switching to EVs.\(^5\)

Moreover, a September 2020 economic report published by the Virginia Tech Office of Economic Development found that enabling drone delivery in a single metropolitan area could avoid up to 294 million miles per year in road use and up to 580 car crashes per year, equivalent to taking 25,000 cars off the road or planting 46,000 acres per year of new forest, reducing carbon emissions by up to 113,900 tons per year.\(^5\) In addition, UAS also play an increasingly important role in reducing global greenhouse gas emissions associated with infrastructure construction and sustainment.\(^5\)

The CDA agrees with the FAA’s conclusions in the draft PEA that for each of the environmental impact categories analyzed—including air quality, biological resources (wildlife), climate, Department of Transportation Act, Section 4(f) Resources, noise and compatible land use, and visual effects (including light emissions)—the environmental effects of the UAS operations in a proposed FRIA location would not meet the FAA’s significance thresholds (where one has been established) or otherwise result in adverse impacts. Therefore, the CDA urges the FAA to finalize its preliminary determination that there will not be a significant impact to the human environment, individually or cumulatively, as a result of UAS operations at FRIAs, and issue a Finding of No Significant Impact.

With this PEA, the FAA is taking important steps to support the UAS industry’s viability and to enable safe, efficient and environmentally friendly commercial UAS operations that will benefit the American public. The CDA looks forward to continuing to work with the FAA to move UAS integration forward safely and securely.

Comment noted.

---

May 4, 2023

The Small UAV Coalition ("Coalition") is pleased to submit these comments in general support of the FAA's use of programmatic environment assessments ("PEAs") in the context of drone operations and in specific support of the use of PEAs for the FAA's establishment of defined geographic areas over which drones may operate without being equipped with remote identification ("remote ID"), so-called "FAA recognized identification areas," or "FRIAs." 88 Fed. Reg. 19708 (Apr. 3, 2023).

In previous comments on draft EAs for the issuance of operations specifications ("op specs"), the Coalition has recommended that the FAA develop clear and transparent drone-specific guidance on compliance with the National Environmental Policy Act ("NEPA") to inform its environmental reviews and to consider the development of a broad programmatic environmental assessment in connection with the authorization of drones with similar environmental footprints. The Coalition appreciates that the FAA is appropriately advancing the use of programmatic NEPA reviews in this matter as encouraged by the Council on Environmental Quality ("CEQ"), which provide for the use of "program-level environmental analysis when projects are similar to each other and have similar impacts."

As stated in the Federal Register notice, the FAA "intends for this PEA to create efficiencies by establishing a framework that can be used for 'tiering,' where appropriate, to project-specific actions that require additional analysis." Id. See also, 40 C.F.R. 1508.1 (ff) (definition of "tiering")

In the draft FRIAs PEA, the FAA has concluded that nine of the fourteen areas of potential environmental impacts do not warrant any detailed consideration. This same conclusion was made in EAs for the issuance of op specs for several drone air carrier operations. For the other areas, such as noise impacts, section 4(f) resources, and visual impacts, the FAA's conclusion in this PEA for FRIAs is the same as the FAA has reached in the drone air carrier EAs.

For noise impacts, the FAA concluded that such impacts in FRIAs will be "well below the FAA's significance threshold of DNL 65 dB." With respect to section 4(f) resources, the Coalition agrees with the FAA's conclusion that "infrequent UAS overflights ... are not a constructive use of any section 4(f) resource, and would not cause any substantial impairment to any of the section 4(f) resources in the study area." Concerning visual impacts, the Coalition agrees that a drone that is seen only up to 6 seconds from a height above trees and power lines at any point is not likely to have any significant visual impact, and in any event would be similar to the sight of legacy aircraft operating at much higher altitudes in the same area. These are findings the FAA has consistently made in drone air carrier EAs.

Because of the many similarities in environmental impacts from drones operating in FRIAs around the country, the FAA is proposing to use a programmatic EA to discharge its NEPA responsibilities, using the concept of tiering in case a particular FRIA requires additional environmental analysis, as outlined in CEQ guidelines and guidance in FAA Order 1050.1 F. The Coalition believes that environmental assessments of drone operations in connection with amending Part 135 drone air carrier op specs to permit BVLOS operations over specifically defined areas bear similarities, both in terms of the environmental categories for which no detailed analysis is necessary and in other environmental categories for which further analysis is required. With respect to noise, visual impacts, and other environmental categories, there does not appear to be any material difference between a drone equipped with remote ID and one that is not equipped with remote ID. While there may instances where the scope, scale, and/or nature...
of the drone operations raise one or more environmental concerns, the FAA can employ tiering in those instances.
